Introduction to containerized NWP system and case study overview

Introduction to containerized NWP system components

WPS, GSI, WRF, UPP, NCL, MET, METviewer

WRF Preprocessing System (WPS)

What is WPS?

- The WRF Preprocessing System (WPS) takes existing 4-d atmospheric data from GRIB-format files and interpolates it onto the user's specified WRF domain grid.
 - Initial conditions: 3-dimensional wind, temperature, geopotential height and RH, 2-dimensional surface pressure
 - Boundary conditions for the parent domain for the full length of the forecast
 - Commonly used input datasets are forecast output from GFS, or reanalysis datasets from NCEP or ECMWF

Function of WPS components

- geogrid.exe (think <u>geo</u>graphical)
 - Define size/location of coarse domain and interpolate static terrestrial fields to coarsedomain and nested-domain grids
- ungrib.exe
 - Extract meteorological fields from GRIB files
- metgrid.exe (think <u>met</u>eorological)
 - Horizontally interpolate meteorological fields (from ungrib) to coarse grid (defined by geogrid)

Gridpoint Statistical Interpolation (GSI) data assimilation

What is GSI?

- Gridpoint Statistical Interpolation (GSI) is the operational data assimilation system being used at NOAA and NCEP-EMC, and can be applied for global and regional analysis, and can also serve as the observation operators for the Ensemble Kalman Filter (EnKF)
- In short, data assimilation takes a forecast (aka, first guess or background field) and modifies the model state based on observations.
 - The difference between the forecast and the observations at the initial time is called the innovation.
 - After applying a weighting function to the innovation and correcting the forecast, an analysis, or best estimate of the initial stat, is created.

GSI analysis increment (analysis-background) after assimilating conventional observations

What does GSI do?

- For WRF applications, GSI can use the output from real.exe (i.e., wrfinput_d01) as the background field, and update it using the various observations. The updated background field so called GSI analysis can then be used as the initial conditions for WRF forecasts
- GSI can also use the WRF forecast files (i.e., wrfout_d01_<yyyymmdd_hh:mm:ss>) as the background fields and update it for further forecasts.
- The observations can include conventional observations, satellite radiance, GPS radio occultations, etc.

Weather Research and Forecasting (WRF) model

What is WRF?

- The Weather Research and Forecasting (WRF) model is a numerical weather prediction model for weather research and forecasting
- Two dynamical cores, both non-hydrostatic
 - Advanced Research WRF (ARW), most commonly used
 - Nonhydrostatic Mesoscale Model (NMM), used in some operational forecasting systems
- Highly configurable, but also caters to less advanced users
 - e.g. 26 different microphysics schemes, 10 surface layer schemes, etc.
 - "Suites" of widely-used and tested scheme combinations are provided for casual users
 - Most options can be easily changed at runtime (no recompilation required)
- Typically run for regional domains, although a global capability exists
 - One parent domain gets its initial and boundary conditions from the WRF Preprocessing System (WPS)
 - Can also have one or more child domains that get their boundary conditions from the parent domain

Function of WRF components

- real.exe
 - Generation of initial state for each of the requested domains
 - Creation of a lateral boundary file for the most coarse domain
 - Vertical interpolation for 3d meteorological fields and for subsurface soil data
- wrf.exe
 - Forecast model integration through time

What is UPP?

- The Unified Post-Processor (UPP) is a post-processor for WRF and other models
 - Developed at the National Centers for Environmental Prediction (NCEP) for use in its operational forecasting
 - Also available for community use and development with WRF
- Processes raw model output to more useful forms
 - Produces hundreds of products like those used operationally
 - T, Z, humidity, wind, cloud water, cloud ice, rain, and snow on isobaric levels
 - SLP + shelter level T, humidity, and wind fields
 - Precipitation-related fields
 - PBL-related fields
 - Diagnostic products (i.e. RH, radar reflectivity, CAPE)
 - Radiative/Surface fluxes 7) Cloud related fields 8) Aviation products
 - Synthetic satellite products
 - Creates output that can be plotted with your favorite visualization tool

Example plots from NCAR Ensemble

NCAR

NCAR 🚛

mble mean 48-hr accumulated snowfall (in

Function of UPP component

- unipost.exe
 - Performs vertical interpolation from model levels/surfaces onto isobaric, height, and other levels/surfaces
 - Calculated derived quantities/diagnostic fields
 - Destaggers wind onto mass points

NCAR Command Language (NCL) visualization

What is NCL?

- The NCAR Command Language
 - An interpreted (scripting) language for creating visualizations of geoscientific data
 - Designed and maintained by the Computational & Information Systems Laboratory (CISL)
 - Can read and write a bunch of different formats (netCDF, HDF4, binary, and ASCII data) and can read many more (HDF5, GRIB1/GRIB2)
 - Supports calling of C and Fortran external routines
 - More info:

https://www.ncl.ucar.edu/overview.shtml

Function of NCL component

- NCL
 - Reads wrfout files created by WRF
 - Calculates derived/accumulated variables (if necessary)
 - Creates plots of one or more variables
 - Can also read grib files created by UPP

Model Evaluation Tools (MET) verification and visualization (METviewer)

What is MET?

- MET is freely available community verification package supported by the DTC
 - Suite of verification tools with over 70 statistics using both point and gridded datasets
 - Full suite of standard statistics with cutting-edge statistics regularly added
 - Computation of confidence intervals
 - Multiple interpolation methods
 - Regridding within the tools and ability to apply complex masking

Object Based and Spatial Methods

90th Percentile of difference between two models

Geographical Representation of Errors

What is METviewer?

- Database and display analysis tool
 - <u>Packages</u>: Java, Apache/Tomcat, MySQL, R statistics

METviewer Plotting example

Case Study Overview

Hurricane Sandy (Initialized on 27 Oct. 2012) Snow case across mid-Atlantic (Initialized on 23 Jan. 2016) Derecho event (Initialized on 29 June 2012)

What cases are provided?

- Three cases with full datasets are provided in current inventory
 - Hurricane Sandy (Initialized on 27 Oct. 2012)
 - 40-km domain centered over East Coast (6-h forecast)
 - Snow case across the mid-Atlantic region (Initialized on 23 Jan. 2016)
 - 30-km CONUS domain (24-h forecast)
 - Derecho event over the Eastern CONUS (Initialized on 29 June 2012)
 - 12-km parent domain with 3-km nest over southern Ohio (24-h forecast)

Sandy Event Background

- Most deadly and destruction hurricane during the 2012 Atlantic hurricane season
 - 230 direct/indirect fatalities
 - Category 1 over Jamaica
 - Impacted Cuba as a Category 3
 - Weakened to a Category 1 over the Bahamas
 - Curved northwest and came onshore in New Jersey with hurricane force winds (no longer tropical)

Snow Event Background

- Classic set-up for a major winter storm
 - Developed near the Gulf Coast and strengthened rapidly as it moved slowly up the coast
 - Produced significant amounts of snow, sleet, and freezing rain
 - Maximum amounts of 30-42" of snow in the mountains near the border of VA/WV/MD

Derecho Event Background

- Progressive derecho originated in Midwest, moved ESE across the Ohio Valley into the Mid-Atlantic
 - Traversed over 700 miles over 10 states
 - 13 deaths directly associated with storm
 - 4 million lost power
- Operational forecast guidance:
 - Global Forecast System (GFS) and NAM did not provide much forecast assistance more than 24 hours out from the event
 - High-Resolution Rapid Refresh (HRRR) model forecast an MCS to move through impacted area on morning of 29 June 2012 → however, previous performance by HRRR did not allow for much confidence in forecast
