Introduction

1.1 HWRF System Overview

The Weather Research and Forecast (WRF) system for hurricane prediction (HWRF) is an operational model implemented at the National Centers for Environmental Prediction (NCEP) of the National Weather Service (NWS) to provide numerical guidance to the National Hurricane Center for the forecasting of tropical cyclones’ track, intensity, and structure. HWRF v3.7a and this Users’ Guide contain the capabilities of, and information regarding, the operational 2015 implementation of HWRF.

The HWRF model is a primitive-equation, non-hydrostatic, coupled atmosphere-ocean model with an atmospheric component that employs the Non-hydrostatic Mesoscale Model (NMM) dynamic core of the WRF model (WRF-NMM), with a parent and two nest domains. The parent domain covers roughly 80° x 80° on a rotated latitude/longitude E-staggered grid. The location of the parent domain is determined based on the initial position of the storm and on the National Hurricane Center (NHC)/Joint Typhoon Warning Center (JTWC) forecast of the 72-h position, if available. The middle nest domain, of about 12° x 12°, and the inner nest domain, of about 7.1° x 7.1°, move along with the storm using two-way interactive nesting. The stationary parent domain has a grid spacing of 0.135° (about 18 km) while the middle nest grid spacing is 0.045° (about 6 km) and the inner nest grid spacing is 0.015° (about 2 km). The dynamic time steps are 38, 12.66, and 4.22 s, respectively, for the parent, middle nest, and inner nest domains. The model top and number of vertical levels used in operations is dependent on the basin. In the north Atlantic (AL), north Eastern Pacific (EP), and north Central Pacific (CP) basins, model top is 2 hPa and 61 levels are used. In all other basins, model top is 50 hPa and 43 levels are used. The system is flexible so that different model tops and number of vertical levels can be used. Additionally, backwards
1. Introduction

compatibility has been maintained such that lower-resolution configurations (i.e., 27/9/3 km) are still supported.

The model physics originated primarily from the Geophysical Fluid Dynamics Laboratory (GFDL) hurricane model, and includes a simplified Arakawa-Schubert scheme for cumulus parameterization and a Ferrier-Aligo cloud microphysics package for explicit moist physics. The vertical diffusion scheme is based on Troen and Mahrt's non-local scheme. The Monin-Obukhov scheme is used for surface flux calculations, which also employs an improved air-sea momentum flux parameterization in strong wind conditions, and the Noah land surface model. Radiation effects are evaluated by the RRTMG scheme, which includes diurnal variations and interactive effects of clouds. The HWRF physics operational suite also includes parameterization of dissipative heating.

The time integration is performed with a forward-backward scheme for fast waves, an implicit scheme for vertically propagating sound waves, and the Adams-Bashforth scheme for horizontal advection and for the Coriolis force. In the vertical, the hybrid pressure-sigma coordinate is used. Horizontal diffusion in based on a 2nd order Smagorinsky-type, for more details see the HWRF Scientific Documentation at http://dtcenter.org/HurrWRF/users/.

HWRF is now running for all global basins in operations at NCEP. This has led NCEP to choose different configurations of HWRF for different global basins. The default configuration of HWRF is based on the full capabilities of HWRF to run for the AL and EP basins, with reduced complexity in all other basins. The following discussion outlines the Atlantic configuration, while section 3.8 describes alternate configurations for other basins.

Model initialization is comprised of both a vortex improvement procedure and data assimilation. The NCEP Global Forecast System (GFS) analysis is used to generate the initial conditions (ICs) for the hurricane model parent domain in the operational configuration. On the inner 6-km and 2-km nests, the NCEP Global Data Assimilation System (GDAS) 6-hour forecast initialized 6 hours prior to the HWRF analysis is interpolated to the appropriate grid and is used as the first guess.

The analysis is modified by first separating the vortex and environment fields of the respective first guess on each domain, i.e. the GFS vortex is separated from the environment on the parent domain, the GDAS vortex is removed from the environment on the inner domains. A new vortex is then incorporated onto the environment field. The new vortex that is added to the environment depends on the observed intensity of the cyclone, and on the existence of a previous HWRF forecast. The new vortex may derive from a bogus procedure, from the 6-h forecast of the HWRF model initialized 6-h previously (referred to as cycling), or from the GDAS 6-h forecast initialized 6 hours previously. In any case, the vortex is modified so that the initial storm position, structure, and intensity conform to the storm message. Cycling the vortex from NHC areas of investigation (invests) to numbered storms is supported.

The first guess with an improved vortex is modified using the HWRF Data Assimilation System (HDAS) by ingesting observations in a three-dimensional (3D) hybrid ensemble-variational (VAR) data assimilation system called Gridpoint Statistical Interpolation (GSI). HWRF assimilates conventional observations, reconnaissance dropsondes, Tail Doppler Radar (TDR), and satellite observations. The information for the flow-dependent back-
1. Introduction

ground error covariance is obtained from the GFS ensemble. HWRF assimilates conventional observations, reconnaissance dropsondes, TDR, and satellite observations. Starting in 2015, when TDR data are present, the operational HWRF uses a 40-member HWRF ensemble instead of the GFS ensemble. Due to the complexity and high use of computational resources to generate the HWRF ensemble, the capability is not supported as part of the HWRF v3.7a public release. The assimilation of TDR data using HWRF v3.7a can be performed using the GFS ensemble. Satellite observations utilized by HWRF include radiances from infrared instruments (HIRS, AIRS, IASI, and GOES sounders) and microwave instruments (AMSU-A, MHS, and ATMS), satellite-derived wind, and Global Positioning System (GPS) radio occultation bending angle. First Guess at Appropriate Time (FGAT) is used to ensure that GSI uses innovations calculated by comparing observations with corresponding model analysis fields valid at the time when the observations were collected. The GFS forecast fields are used to provide lateral boundary conditions every 6 hours during the forecast.

The Community HWRF model can be used in atmosphere-ocean coupled mode for all oceanic basins. The MPIPOM-TC ocean model implements Message Passing Interface (MPI) to run a parallel version of the Princeton Ocean Model (POM) for Tropical Cyclones (POM-TC). The POM was developed at Princeton University. At the University of Rhode Island (URI), the POM was coupled to the GFDL and WRF models. In all basins, MPIPOM-TC is run in three dimensions with 1/12° (approximately 9-km) horizontal grid spacing. The MPIPOM-TC is configured with 23 vertical levels. The default HWRF is configured to run in coupled mode only in the AL and EP basins. However, coupling can be enabled with HWRF v3.7a in any basin.

The MPIPOM-TC is initialized in any basin by a diagnostic and prognostic spin up of the ocean circulations using climatological ocean data. For storms located in the western part of the Atlantic basin, the initial conditions are enhanced with real-time sea surface temperature (SST), sea surface height data, and the assimilation of oceanic “features”. During the ocean spin up, realistic representations of the structure and positions of the Loop Current, Gulf Stream, and warm- and cold-core eddies are incorporated using a features-based data assimilation technique developed at URI.

The atmospheric and oceanic components are interactively coupled with a Message Passing Interface (MPI)-based coupler, which was developed at NCEP’s Environmental Modeling Center (EMC). The atmospheric and oceanic components exchange information through the coupler; the ocean sends the SST to the atmosphere; the atmosphere receives the SST and sends the surface fluxes, including sensible heat flux, latent heat flux and short-wave radiation to the ocean, and so on. The frequency of information exchange is nine minutes.

HWRF is suitable for use in tropical applications including real-time NWP, forecast research, physics parameterization research, air-sea coupling research, and teaching. Additionally, the capability to perform idealized tropical cyclone simulations is included. The HWRF system support to the community by the Developmental Testbed Center (DTC) includes the following four main modules:

- HWRF atmospheric components
  - WRF-NMM (which has tropical physics schemes and a vortex-following moving nest)
  - WRF Preprocessing System (WPS)
1. Introduction

- Vortex initialization
- GSI
- Unified Post-Processor (UPP)
- GFDL vortex tracker

• HWRF oceanic components
  - MPIPOM-TC model
  - Ocean initialization
• Atmosphere-Ocean Coupler
• HWRF Run Module

The run module includes scripts in the Python language. The NCEP 2015 operational implementation of HWRF and the HWRF v3.7a are almost identical with the exception that starting in 2015, NCEP runs an HWRF ensemble for the assimilation of TDR data – a capability that is not currently supported to the community. Due to the novel nature of these scripts, users should expect some additions and changes in the upcoming months. Those will be posted in the Frequently-Asked-Questions (FAQ) or Known Issues sections of the DTC website at http://dtcenter.org/HurrWRF/users.

1.2 HWRF Development and Support

All HWRF components are under the Subversion revision control system. The code repositories are hosted and maintained as community codes at the National Center for Atmospheric Research (NCAR), except for GSI, which is housed at the National Oceanic and Atmospheric Administration (NOAA). An HWRF code management protocol has been established for proposing HWRF-related modifications to the software, whether the modifications are simply updates to the current features, bug fixes, or the addition of new features. HWRF code development must be carried out in the branches of the repositories and frequently synchronized with the trunks. Proposed software modifications must be thoroughly tested prior to being committed to the code repository to protect the integrity of the evolving code base. Advanced users interested in contributing to the HWRF system are encouraged to visit the HWRF Developers page at http://www.dtcenter.org/HurrWRF/developers/index.php to get more information on the protocols of HWRF development.

HWRF is being actively developed and advanced. In the future, more components will be coupled into the HWRF system, including wave, hydrology, storm surge, and inundation components.

The HWRF modeling system software is in the public domain and is freely available for community use. Information about obtaining the codes, datasets, documentation, and tutorials can be found at http://www.dtcenter.org/HurrWRF/users and in the following chapters of this Users’ Guide. Please refer to http://www.dtcenter.org/HurrWRF/users/support/index_help.php on how to contact HWRF helpdesk.
1. Introduction

1.3 HWRF Source Code Directory Structure

The HWRF system source code has the following nine components:

- WRF Atmospheric Model
- WPS
- UPP
- GSI
- HWRF Utilities
- MPIPOM-TC
- GFDL Vortex Tracker
- NCEP Atmosphere-Ocean Coupler
- HWRF Run Component

The code for all components can be obtained by downloading the following tar files from the DTC website (see Chapter 2 for installation information):

- HWRF_v3.7a_WRFV3.tar.gz
- HWRF_v3.7a_WPSV3.tar.gz
- HWRF_v3.7a_UPP.tar.gz
- HWRF_v3.7a_GSI.tar.gz
- HWRF_v3.7a_hwrf-utilities.tar.gz
- HWRF_v3.7a_gfdl-vortextracker.tar.gz
- HWRF_v3.7a_ncep-coupler.tar.gz
- HWRF_v3.7a_pomtc.tar.gz
- HWRF_v3.7a_hwrfrun.tar.gz

First expand `HWRF_v3.7a_hwrfrun.tar.gz` in a user-defined HWRF top directory. Once completed, change directory to `$(SCRATCH)/hwrfrun/sorc` to expand the remaining tar files. The following directories should be present once all files are expanded:

- WRFV3 – Weather Research and Forecasting model
- WPSV3 – WRF Preprocessing System
- UPP – Unified Post-Processor
- GSI – Gridpoint Statistical Interpolation hybrid ensemble 3D-VAR data assimilation
- hwrf-utilities – Vortex initialization, utilities, tools, and supplemental libraries
- gfdl-vortextracker – Vortex tracker
- ncep-coupler – Ocean/atmosphere coupler
- pomtc – Tropical cyclone version of MPIPOM

For the remainder of this document, we assume that the tar files have been expanded under `$(SCRATCH)/hwrfrun/sorc`, where `$(SCRATCH)` is an environment variable that describes the location of the directory in which you installed the HWRF components.

The directory trees for these nine components are listed as follows. Note that these are the directories after the code is compiled. Before compilation not all of these directories are present.

hwrfrun/
1. Introduction

- **nwport/** extra utilities for HWRF used in operations.
- **parm/** files to configure HWRF experiment
- **scripts/** Python scripts to run the HWRF components
- **sorc/** empty directory where HWRF components’ code should be placed
- **ush/** Python modules
- **hwrf/** HWRF-specific Python modules
- **produtils/** HWRF-independent Python modules for generalization of platforms and systems
- **wrappers/** sh wrapper scripts used to run the Python scripts
Software Installation

2.1 Introduction

The DTC community HWRF system, which is based on the NOAA operational HWRF, consists of nine components:

- WRF Atmospheric Model
- WPS
- UPP
- GSI
- HWRF-utilities
- MPIPOM-TC
- GFDL Vortex Tracker
- NCEP Atmosphere-Ocean Coupler
- HWRF Run

The first three of these components are the traditional WRF components: Weather Research and Forecasting model (WRF), WRF Preprocessing System (WPS), and Unified Post-Processor (UPP). Gridpoint Statistical Interpolation (GSI) is a 3D variational data assimilation code used for data assimilation, and the remaining four components are specific to the hurricane system itself, and as such are referred to as the hurricane components of the HWRF system.

This chapter discusses how to build the HWRF system. It starts in section 2.2 with a description of where to find the source code. Section 2.3 covers the preferred directory structure and how to unpack the tar files. Section 2.4 covers the system requirements for building and running the components. Section 2.5 discusses the libraries included in the HWRF-utilities component. Section 2.6 explains how to build WRF-NMM for HWRF. The remaining sections are devoted to building each of the remaining components of the HWRF system.
2. Software Installation

2.2 Obtaining the HWRF Source Code

The HWRF hurricane system consists of nine components. All of these are available from the HWRF website,

http://www.dtcenter.org/HurrWRF/users.

While most of these codes are also available from other community websites, the versions needed for HWRF should be acquired from the DTC HWRF website to ensure they are a consistent set.

To download HWRF, select the "Download" and "HWRF System" tabs on the left vertical menu of the HWRF Users' Website. New users must first register before downloading the source code. Returning users need only provide their registration email address. A successful download produces nine tar files:

- HWRF_v3.7a_WRFV3.tar.gz
- HWRF_v3.7a_WPSV3.tar.gz
- HWRF_v3.7a_UPP.tar.gz
- HWRF_v3.7a_GSI.tar.gz
- HWRF_v3.7a_hwrfrun.tar.gz
- HWRF_v3.7a_hwrfrun.tar.gz
- HWRF_v3.7a_gfdl-vortextracker.tar.gz
- HWRF_v3.7a_ncep-coupler.tar.gz
- HWRF_v3.7a_pomtc.tar.gz

After downloading each of the component codes, the user should check the links to "Known Issues" and "Bug Fixes" to see if any code updates are required. You now have all the HWRF system components as gzipped tar files. The next section describes how to organize them.

2.3 Setting up HWRF

Although the HWRF scripts may be modified for any directory structure, in this discussion, we assume that the HWRF system will be set up in a single flat directory structure. Because of the storage requirements necessary for the complete HWRF system setup, it will typically need to be located on a computer's “scratch” or “work” partition.

The tar files can be unpacked by use of the GNU gunzip command,

```
gunzip *.tar.gz
```

and the tar files extracted by running `tar -xvf` individually on each of the tar files. The User should first unpack hwrfrun, which will create a directory `hwrfrun/` in `${SCRATCH}`. Then within `${SCRATCH}/hwrfrun/sorc/` directory, unpack the remaining tar files.
2. Software Installation

Once unpacked, there should be eight source directories in `sorc/`.

- **WRFV3** – Weather Research and Forecasting model
- **WPSV3** – WRF Preprocessing System
- **UPP** – Unified Post-Processor
- **GSI** – Gridpoint Statistical Interpolation
- **hwrf-utilities** – Vortex initialization, utilities, tools, and supplemental libraries
- **gfdl-vortextracker** – Vortex tracker
- **ncep-coupler** – Ocean/atmosphere coupler
- **pomtc** – Tropical cyclone version of MPIOM

The next section covers the system requirements to build the HWRF system.

2.4 System Requirements, Libraries, and Tools

In practical terms, the HWRF system consists of a collection of Python modules, which runs a sequence of serial and parallel code executables. The source code for these executables is in the form of programs written in FORTRAN, FORTRAN 90, and C. In addition, the parallel executables require some flavor of MPI/OpenMP for the distributed memory parallelism, and the I/O relies on the netCDF I/O libraries. Beyond the standard scripts, the build system relies on use of the Perl scripting language, along with GNU make and date.

The basic requirements for building and running the HWRF system are listed below:

- **FORTRAN 90+ compiler**
- **C compiler**
- **MPI v1.2+**
- **Perl**
- **netCDF v3.6+**
  - if netCDF v4.1+ is used, HDF5 and SZIP libs may also be required
- **LAPACK and BLAS**
- **Python**
- **Parallel-netCDF**
- **PNG**
- **JasPer**
- **zlib**

Because these tools and libraries are typically the purview of system administrators to install and maintain, they are considered part of the basic system requirements.

2.4.1 Compilers

The DTC community HWRF system has been tested on a variety of computing platforms. Currently the HWRF system is actively supported on Linux computing platforms using both the Intel and PGI Fortran compilers. Unforeseen build issues may occur when using older
2. Software Installation

compiler versions. Typically the best results come from using the most recent version of a compiler. Please note: A PGI version of at least 13.2 is required to build the HWRF system. The "Known Issues" section of the community website provides the complete list of compiler versions currently supported.

While the community HWRF build system provides legacy support for the IBM AIX platforms, the unavailability of AIX test platforms means all AIX support is cursory at best.

2.4.2 netCDF, pnetCDF, and MPI

The HWRF system requires a number of support libraries not included with the source code. Many of these libraries may be part of the compiler installation, and are subsequently referred to as system libraries. For our needs, the most important of these libraries are netCDF, pnetCDF, and MPI.

An exception to the rule of using the most recent version of code, libraries, and compilers is the netCDF library. The HWRF system I/O requires the most recent V3 series of the library. The preferred version of the library is netCDF v3.6+. The netCDF libraries can be downloaded from the Unidata website.

http://www.unidata.ucar.edu

Typically, the netCDF library is installed in a directory that is included in the users path such as /usr/local/lib. When this is not the case, the environment variables NETCDF and PNETCDF can be set to point to the location of the library.

For csh/tcsh, the path can be set with the following command:

```
setenv NETCDF path_to_netcdf_library/
setenv PNETCDF path_to_pnetcdf_library/
```

For bash/ksh, the equivalent command is as follows:

```
export NETCDF=path_to_netcdf_library/
export PNETCDF=path_to_pnetcdf_library/
```

It is crucial that system libraries, such as netCDF, be built with the same FORTRAN compiler, compiler version, and compatible flags, as used to compile the remainder of the source code. This is often an issue on systems with multiple FORTRAN compilers, or when the option to build with multiple word sizes (e.g. 32-bit vs. 64-bit addressing) is available.

Many default Linux installations include a version of netCDF. Typically this version is only compatible with code compiled using gcc. To build the HWRF system, a version of the library must be built using your preferred compiler and with both C and FORTRAN bindings. If you have any doubts about your installation, ask your system administrator.
2. Software Installation

Building and running the HWRF distributed memory parallel executables requires that a version of the MPI library be installed. Just as with the netCDF library, the MPI library must be built with the same FORTRAN compiler, and use the same word size option flags, as the remainder of the source code. Installing MPI on a system is typically a job for the system administrator and will not be addressed here. If you are running HWRF on a computer at a large center, check the machine's documentation before you ask the local system administrator.

2.4.3 LAPACK and BLAS

The LAPACK and BLAS libraries are open source mathematics libraries for solving linear algebra problems. The source code for these libraries is freely available to download from NETLIB at

http://www.netlib.org/lapack/.

Most commercial compilers provide their own optimized versions of these routines. These optimized versions of BLAS and LAPACK provide superior performance to the open source versions.

On Linux systems, HWRF supports both the Intel ifort and PGI pgf90 Fortran compilers. The Intel compiler has its own optimized version of the BLAS and LAPACK routines called the Math Kernel Library or MKL. The MKL libraries provide most of the LAPACK and BLAS routines needed by the HWRF system. The PGI compiler typically comes with its own version of the BLAS and LAPACK libraries. Again, the PGI version of BLAS and LAPACK contains most of the routines needed by HWRF. For PGI these libraries are loaded automatically. Since the vendor versions of the libraries are often incomplete, a copy of the full BLAS library is provided with the HWRF-utilities component. The build system links to this version of the libraries last.

On the IBM machines, the AIX compiler is often, but not always, installed with the Engineering and Scientific Subroutine Libraries or ESSL. In part, the ESSL libraries are highly optimized parallel versions of many of the LAPACK and BLAS routines. The ESSL libraries provide all of the necessary linear algebra library routines needed by the HWRF system.

2.5 Included Libraries

For convenience in building HWRF-utilities, the MPIPOM-TC, and the GFDL Vortex Tracker components, the HWRF-utilities component includes a number of libraries in the hwrf-utilities/libs/src/ directory. The following libraries are built automatically when the HWRF-utilities component is built:

- BACIO
2. Software Installation

- BLAS
- BUFR
- SFCIO
- SIGIO
- SP
- W3
- G2

The other components, WPS, WRF, UPP, and GSI, come with their own versions of many of these libraries, but typically they have been customized for that particular component and should not be used by the other components.

When the HWRF-utilities component is compiled, it starts by first building all the included libraries. The vortex initialization code contained in the HWRF-utilities component requires all of the above libraries except for the SFCIO library. In addition, it requires both the BLAS and LAPACK mathematical libraries when the IBM ESSL library is not included with the compiler installation.

The MPIPOM-TC component requires the SFCIO, SP and W3 libraries. In addition, the local copy of the BLAS library is required when the ESSL library is not included with the compiler installation. This is because the vendor-supplied versions of BLAS are typically incomplete, and the local version supplements the vendor version. Typically this is for any system other than IBM. The GFDL vortex tracker component requires the BACIO and W3 libraries. The NCEP-Coupler does not require any additional libraries.

2.5.1 Component Dependencies

The eight components of the HWRF system that contain source code have certain inter-dependencies. Many of the components depend on libraries produced by other components. For example, four of the components, WPS, UPP, GSI, and the HWRF-utilities, require linking to the WRF I/O API libraries to build. Since these I/O libraries are created as part of the WRF build, the WRF component must be built first. Once WRF is built, WPS, UPP, GSI, or the HWRF-utilities can be built in any order. Since building the HWRF-utilities produces the supplemental libraries needed by MPIPOM-TC and by the GFDL Vortex Tracker, the HWRF-utilities must be built before either of these components. The remaining component, the NCEP Coupler, can be built independently of any of the other components. The main system component dependency is as follows:

- WRF
  - WPS
  - UPP
  - GSI
  - HWRF-utilities
    * MPIPOM-TC (BLAS on Linux, sfcio, sp, w3)
    * GFDL vortex tracker (w3, bacio, G2)
- NCEP Coupler
2.6 Building WRF-NMM

The WRF code has a fairly sophisticated build mechanism. The package attempts to determine the machine where the code is being built, and then presents the user with supported build options on that platform. For example, on a Linux machine, the build mechanism determines whether the machine is 32-bit or 64-bit, prompts the user for the desired type of parallelism (such as serial, shared memory, distributed memory, or hybrid), and then presents a selection of possible compiler choices.

In addition, the user may choose to run WRF with either real or idealized input data. The idealized data case requires setting environment flags prior to compiling the code, which creates a unique executable that should only be run with the idealized data. See section 2.6.3 for compiling WRF for ideal runs.

2.6.1 Set Environment Variables

To correctly configure WRF-NMM for the HWRF system, set the following additional environment variables beyond what WRF typically requires.

In C-Shell use the following commands:

```bash
setenv HWRF 1
setenv WRF_NMM_CORE 1
setenv WRF_NMM_NEST 1
setenv JASPERLIB path_to_jasper_library/
setenv JASPERINC path_to_jasper_includes/
setenv PNETCDF_QUILT 1
setenv WRFIO_NCD_LARGE_FILE_SUPPORT 1
```

Add the following command for IBM AIX builds using C-Shell:

```bash
setenv IBM_REDUCE_BUG_WORKAROUND 1
```

In Bash shell, use the following commands:

```bash
export HWRF=1
export WRF_NMM_CORE=1
export WRF_NMM_NEST=1
export JASPERLIB=path_to_jasper_library/
export JASPERINC=path_to_jasper_includes/
export PNETCDF_QUILT=1
export WRFIO_NCD_LARGE_FILE_SUPPORT=1
```

Add the following command for IBM AIX builds using Bash:

```bash
export IBM_REDUCE_BUG_WORKAROUND=1
```
2. Software Installation

These settings produce a version of WRF-NMM compatible with the HWRF system.

There is a bug in the IBM MPI implementation. Some MPI processes will get stuck in MPI_Reduce and not return until the PREVIOUS I/O server group finishes writing. When the environment variable $\text{IBM\_REDUCE\_BUG\_WORKAROUND}=1$, a workaround is used that replaces the MPI_Reduce call with many MPI_Send and MPI_Recv calls that perform the sum on the root of the communicator.

Note that setting the environment variable $\text{WRF\_NMM\_NEST}$ to 1 does not preclude running with a single domain.

2.6.2 Configure and Compile WRF-NMM

To configure WRF-NMM, go to the top of the WRF directory (cd ${SCRATCH}/hwrfrun/sorc/WRFV3) and use the following command:

```
./configure
```

You will be presented with a list of build choices for your computer. These choices may include multiple compilers and parallelism options.

For Linux architectures, there are currently 63 options. For the HWRF system, only the distributed memory (dmpar) builds are valid. Therefore as an example, the acceptable Intel options (15, 20, 24, and 28) are shown below:

13. (serial) 14. (smpar) 15. (dmpar) 16. (dm+sm) INTEL (ifort/icc)
22. (serial) 23. (smpar) 24. (dmpar) 25. (dm+sm) INTEL (ifort/icc): SGI MPT
26. (serial) 27. (smpar) 28. (dmpar) 29. (dm+sm) INTEL (ifort/icc): IBM POE

The configure step for the WRF model is now completed. A file has been created in the WRF directory called `configure.wrf`. The compile options and paths in the `configure.wrf` file can be edited for further customization of the build process.

To build the WRF-NMM component enter the following command:

```
./compile nmm_real
```

In general, it is good practice to save the standard out and error to a log file for reference. In the csh/tcsh shell this can be done with the following command:

```
./compile nmm_real |& tee build.log
```

For the ksh/bash shell use the following command:

```
./compile nmm_real 2>&1 | tee build.log
```
In both cases, the standard out and the standard error are sent to both the file `build.log` and to the screen. The approximate compile time varies according to the system being used and the aggressiveness of the optimization. On IBM AIX machines, the compiler optimization significantly slows down the build time, and it typically takes at least half an hour to complete. On most Linux systems, the WRF model typically compiles in around 20 minutes.

It is important to note that the commands `./compile -h` and `./compile` produce a listing of all of the available compile options, but only the `nmm_real` option is relevant to the HWRF system.

A successful compilation produces two executables listed below in the directory `main/`.

- `real_nmm.exe`  WRF initialization
- `wrf.exe`  WRF model integration

If a recompilation is necessary, a clean to remove all object files (except those in `external/`) should be completed first:

```
./clean
```

A complete clean is strongly recommended if the compilation failed, the Registry has been changed, or the configuration file is changed. To conduct a complete clean that removes all built files in all directories, as well as the `configure.wrf` use the "-a" option:

```
./clean -a
```

Further details on the HWRF atmospheric model, physics options, and running the model can be found in the Running HWRF chapter of the Users’ Guide.

Complete details on building and running the WRF-NMM model are available in the WRF-NMM Users’ Guide, which is available here:

### 2.6.3 Configure and Compile: Idealized Tropical Cyclone WRF-NMM

The HWRF idealized tropical cyclone WRF-NMM component requires different executables than for the real case. The following section will describe how to build the executables for the idealized case.

Building the idealized component requires a slightly different configuration than for the standard WRF build outlined in section 2.6.1. If a user has already built the standard WRFV3 and created `real_nmm.exe` and `wrf.exe`, and now wants to build WRFV3 for idealized tropical cyclone simulations, they first need to completely clean the previous build. This is done by typing:
2. Software Installation

./clean -a

which removes ALL build files, including the executables, libraries, and the configure.hwrf. To correctly configure WRF-NMM for the HWRF idealized tropical cyclone simulation requires setting the additional environment variable IDEAL_NMM_TC. Several other variables must also be set.

In C-Shell use the following commands:

```bash
setenv WRF_NMM_CORE 1
setenv WRF_NMM_NEST 1
setenv HWRF 1
setenv IDEAL_NMM_TC 1
setenv WRFIO_NCD_LARGE_FILE_SUPPORT 1
```

The following commands should be used for bash/ksh:

```bash
export WRF_NMM_CORE=1
export WRF_NMM_NEST=1
export HWRF=1
export IDEAL_NMM_TC=1
export WRFIO_NCD_LARGE_FILE_SUPPORT=1
```

To configure WRF-NMM, go to the top of the WRF directory (`cd ${SCRATCH}/hwrfrun/sorc/WRFV3`) before issuing the following command:

```bash
./configure
```

You will be presented with a list of build choices for your computer. These choices may include multiple compilers and parallel options.

For Linux architectures, there are currently 51 options. For the HWRF system, only the distributed memory (`dmpar`) builds are valid. Therefore as an example, the acceptable Intel options (15, 20, 24, 28) are shown below:

13. (serial) 14. (smpar) 15. (dmpar) 16. (dm+sm) INTEL (ifort/icc)
22. (serial) 23. (smpar) 24. (dmpar) 25. (dm+sm) INTEL (ifort/icc): SGI MPT
26. (serial) 27. (smpar) 28. (dmpar) 29. (dm+sm) INTEL (ifort/icc): IBM PE

The configure step for the WRF model is now completed. A file has been created in the WRF directory called `configure.wrf`. The compile options and paths in the `configure.wrf` file can be edited for further customization of the build process.

Once the configure step is complete, the code is compiled by including the target `nmm_tropical_cyclone` to the compile command:

```bash
./compile nmm_tropical_cyclone
```
2. Software Installation

A successful compilation produces two executables in the directory `main/`.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ideal.exe</td>
<td>WRF initialization</td>
</tr>
<tr>
<td>wrf.exe</td>
<td>WRF model integration</td>
</tr>
</tbody>
</table>

Note: The only compilation requirements for the idealized capability are WPS and WRF. If wanted, UPP may also be used. The components MPIPOM-TC and coupler, GSI, GFDL vortex tracker, and HWRF-utilities are not used in HWRF idealized tropical cyclone simulations.

2.7 Building HWRF-utilities

The `hwrf-utilities/` directory consists of an eclectic collection of source code and libraries. The libraries, which are provided in support of the MPIPOM-TC and the GFDL Vortex Tracker, include the BACIO, BLAS, BUFR, SIGIO, SFCIO, SP, and W3 libraries. In addition to these libraries, this component includes the source code for the vortex initialization routines and software tools such as the grbindex.

2.7.1 Set Environment Variables

The HWRF-utilities build requires that two path variables, `NETCDF` and `WRF_DIR`, be set to the appropriate paths. The netCDF library path `NETCDF` is required for building the WRF-NMM component, and its value should be appropriately set if that component compiled successfully. The `WRF_DIR` path variable should point to the WRF directory compiled in the previous section. You must first build WRF before compiling most of the other components.

If you have followed the directory structure suggested in section 2.3, the `WRF_DIR` path should be set to `$SCRATCH/hwrfrun/sorc/WRFV3`. In csh/tcsh, the variables may be set with two commands:

```
setenv NETCDF /absolute_path_to_appropriate_netCDF_library/
setenv WRF_DIR ${SCRATCH}/hwrfrun/sorc/WRFV3
```

For the ksh/bash shells, use the following two commands:

```
export NETCDF=/absolute_path_to_appropriate_netCDF_library/
export WRF_DIR=${SCRATCH}/hwrfrun/sorc/WRFV3
```

It is crucial that the Fortran compiler used to build the libraries (Intel, PGI, XLF, etc.) be the same as the compiler used to compile the source code. Typically, this is only an issue in two situations, on Linux systems having multiple compilers installed, and on systems where there is a choice between building the code with either 32-bit or 64-bit addressing.
2. Software Installation

2.7.2 Configure and Compile

To configure HWRF-utilities for compilation, from within the \texttt{hwrf-utilities} directory, type the following command:

\texttt{./configure}

The configure script checks the system hardware, and if the path variables are not set, asks for the correct paths to the netCDF libraries and the WRF build directory. It concludes by asking the user to choose a configuration supported by current machine architecture.

For Linux, seven options are available.

1. Linux x86_64, PGI compiler w/LAPACK (dmpar)
2. Linux x86_64, PGI compiler w/LAPACK, SGI MPT (dmpar)
3. Linux x86_64, Intel compiler w/MKL (dmpar)
4. Linux x86_64, Intel compiler w/MKL, SGI MPT (dmpar)
5. Linux x86_64, Intel compiler w/MKL, IBM POE (dmpar)
6. Linux x86_64, Intel compiler w/LAPACK (dmpar)
7. Linux x86_64, Intel compiler w/LAPACK, SGI MPT (dmpar)

For the PGI compiler, pick options 1 or 2. For Intel builds, pick option 3, 4, or 5 if your compiler includes the MKL libraries, and option 6 or 7 if it does not.

If successful, the configure script creates a file called \texttt{configure.hwrf} in the \texttt{hwrf-utilities/} directory. This file contains compilation options, rules, and paths specific to the current machine architecture, and can be edited to change compilation options, if desired.

In csh/tcsh, compile the HWRF-utilities and save the build output to a log file:

\texttt{./compile} & tee \texttt{build.log}

For the ksh/bash shell, use the following command:

\texttt{./compile 2>&1 | tee \texttt{build.log}}

If the compilation is successful, it will create the following executables in the directory \texttt{exec/}:

- \texttt{bufr_remorest.exe}
- \texttt{diffwrf_3dvar.exe}
- \texttt{gridparse.exe}
- \texttt{grp_atcf_to_stats.exe}
- \texttt{grp_getcenter.exe}
- \texttt{grp_gridparse.exe}
- \texttt{grp_hwrf_atcf_intensity.exe}
- \texttt{grp_hwrf_atcf_tracks.exe}
- \texttt{grp_inddiag.exe}
- \texttt{grp_inddiagnull.exe}
- \texttt{grp_nameparse.exe}
- \texttt{grp_statsin_domain.exe}
- \texttt{grp_statsin_domain_TI.exe}
- \texttt{grp_totaldiag.exe}
- \texttt{hwrf_afos.exe}
- \texttt{hwrf_anl_4x_step2.exe}
- \texttt{hwrf_anl_bogus_10m.exe}
2. Software Installation

```
hwrf_anl_cs_10m.exe
hwrf_atcf_to_stats.exe
hwrf_aux_rw.exe
hwrf_bdy_update.exe
hwrf_binary_grads.exe
hwrf_bin_io.exe
hwrf_blend_gsi.exe
hwrf_change_prepbufr_qm_in_circle.exe
hwrf_change_prepbufr_qm_typ.exe
hwrf_combinetrack.exe
hwrf_create_trak_fnl.exe
hwrf_create_trak_guess.exe
hwrf_gridgenfine.exe
hwrf_htcfstats.exe
hwrf_inter_2to1.exe
hwrf_inter_2to2.exe
hwrf_inter_2to6.exe
hwrf_inter_4to2.exe
hwrf_inter_4to6.exe
hwrf_merge_nest_4x_step12_3n.exe
hwrf_metgrid_levels.exe
hwrf_netcdf_grads.exe
hwrf_nhc_products.exe
hwrf_old_gettrk.exe
hwrf_pert_ctl1.exe
hwrf_prep.exe
hwrf_read_indi_write_all.exe
hwrf_readtdrtime.exe
hwrf_readtdrtrack.exe
hwrf_readtdrtrigger.exe
hwrf_rem_prepbufr_typ_in_circle.exe
hwrf_split1.exe
hwrf_supvit.exe
hwrf_swath.exe
hwrf_swcorner_dynamic.exe
hwrf_wrfout_newtime.exe
mdate.exe
mpi_example.exe
mpiserial.exe
ndate.exe
nhour.exe
serpoe.exe
wave_sample.exe
wgrib.exe
```

In addition, it will create twelve libraries in the directory `libs/`:

```
libbacio.a — BACIO library
libblas.a — BLAS library
libbufr_i4r4.a — BUFR library built with -i4 Dr4 flags
libbufr_i4r8.a — BUFR library built with -i4 -r8 flags
libg2.a — GRIB2 library
libhwrfutil_i4r4.a — Miscellaneous data manipulation utilities
libsfcio_i4r4.a — SFCIO library built with -i4 -r4 flags
libsigio_i4r4.a — SIGIO library built with Di4 Dr4 flags
libsp_i4r8.a — SP library built with -i4 -r8 flags
libsp_i4r4.a — SP library built with -i4 -r4 flags
libw3_i4r8.a — W3 library built with -i4 -r8 flags
libw3_i4r4.a — W3 library built with -i4 -r4 flags
```

These libraries will be used by the GFDL Vortex Tracker and the MPIPOM-TC ocean model. The configuration step for these components will require setting a path variable to point to the `hwrf-utilities/libs/` directory in the HWRF-utilities directory.

If a recompilation is necessary, a clean to remove all object files (except those in `external/`) should be completed first:

```
./clean
```
2. Software Installation

A complete clean is strongly recommended if the compilation failed, the Registry has been changed, or the configuration file is changed. To conduct a complete clean that removes all built files in all directories, as well as the `configure.hwrf`, use the "-a" option:

```
./clean -a
```

The HWRF-utilities can be compiled to produce only the libraries by typing the command below:

```
./compile library
```

This is useful for users that do not intend to use the entire HWRF system, but just need the libraries to build the tracker.

2.8 Building MPIPOM-TC

2.8.1 Set Environment Variables

The Tropical Cyclone version of the MPIPOM-TC requires four external libraries: SFCIO, SP, W3, and PNETCDF. On platforms that lack the ESSL mathematical libraries, typically anything other than IBM AIX machines, a fifth library (BLAS) is required. The first three of these libraries are located in the `hwrf-utilities/libs/` directory and should be available if the HWRF-utilities component has been built successfully. You must first build them before building MPIPOM-TC.

Set the library paths (assuming the directory structure proposed in section 2.3) using C-Shell:

```
setenv LIB_W3_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv LIB_SP_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv LIB_SFCIO_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv PNETCDF PATH_TO_PNETCDF
```

Similarly, the libraries can be set using the ksh/bash shell:

```
export LIB_W3_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export LIB_SP_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export LIB_SFCIO_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export PNETCDF=PATH_TO_PNETCDF
```

In addition to these libraries, MPIPOM-TC requires linear algebra routines from the BLAS library. When building MPIPOM-TC on an IBM platform, the build will automatically use the ESSL library, which includes highly optimized versions of some of the BLAS routines. When building MPIPOM-TC in a platform without ESSL (such as Linux), the build system uses the BLAS mathematical library provided with the hwrf-utilities component. In such a case, the fifth and final path must be set:

```
setenv LIB_BLAS_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
```
2. Software Installation

For the ksh/bash shells the path can be set similarly:

```
export LIB_BLAS_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
```

2.8.2 Configure and Compile

Configure MPIPOM-TC for compilation from within the pomtc/ directory:

```
./configure
```

The configure script checks the system hardware, and if the path variables are not set, asks for software paths to the W3, SP, SFCIO, and PNETCDF, and for Linux, the BLAS libraries. It concludes by asking the user to choose a configuration supported by current machine architecture.

For the IBM, only one choice is available:

1. AIX (dmpar)

The following options exist for Linux:

1. Linux x86_64, PGI compiler (dmpar)
2. Linux x86_64, PGI compiler, SGI MPT (dmpar)
3. Linux x86_64, Intel compiler (dmpar)
4. Linux x86_64, Intel compiler, SGI MPT (dmpar)
5. Linux x86_64, Intel compiler, IBM POE (dmpar)

After selecting the desired compiler option, the configure script creates a file called configure.pom. This file contains compilation options, rules, and paths specific to the current machine architecture, and can be edited to change compilation options, if desired.

Compile the MPIPOM-TC and save the build output to a log file with csh/tcsh:

```
./compile & tee ocean.log
```

Similarly, for ksh, use the following syntax:

```
./compile 2>&1 | tee ocean.log
```

If the compilation is successful, eleven executables are created in ocean_exec/:

```
gfdl_date2day.exe
gfdl_day2date.exe
gfdl_getsst.exe
gfdl_sharp_mcs_rf_l2m_rmy5.exe
hwrf_ocean_fcst.exe
hwrf_ocean_init.exe
pomprep_fbtr.xc
```
2. Software Installation

pomprep_gdm3.xc
pomprep_hycu.xc
pomprep_idel.xc
pomprep_ncda.xc
readsstuvhflux.xc
transatl06prep.xc

If a recompilation is necessary, a clean to remove all object files should be completed:

./clean

A complete clean is strongly recommended if the compilation failed, the configuration file has been changed, or the configuration file is changed. To conduct a complete clean that removes all built files in all directories, as well as the configure.pom, use the "-a" option.

./clean -a

2.9 Building GFDL Vortex Tracker

2.9.1 Set Environment Variables

The GFDL Vortex Tracker requires two external libraries, W3 and BACIO. These libraries are located in the hwrf-utility/libs/ directory and should be available if the HWRF-utilities are successfully built. You must build the HWRF-utilities before building the vortex tracker.

Again, assuming that the directory structure is the same as that proposed in section 2.3, set the library paths:

```
setenv LIB_W3_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv LIB_BACIO_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv LIB_G2_PATH ${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
setenv LIB_Z_PATH SYSTEM_LOCATION
setenv LIB_PNG_PATH SYSTEM_LOCATION
setenv LIB_JASPER_PATH SYSTEM_LOCATION
```

Similarly, the syntax for the ksh/bash shell can be used:

```
export LIB_W3_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export LIB_BACIO_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export LIB_G2_PATH=${SCRATCH}/hwrfrun/sorc/hwrf-utilities/libs/
export LIB_Z_PATH=SYSTEM_LOCATION
export LIB_PNG_PATH=SYSTEM_LOCATION
export LIB_JASPER_PATH=SYSTEM_LOCATION
```

where SYSTEM_LOCATION should be replaced with the full path to the installed library. On
many systems, these libraries reside in `/usr/lib` or `/usr/lib64`.

2.9.2 Configure and Compile

Configure the Vortex Tracker for compilation from within the `gfdl-vortextracker` directory:

`./configure`

The configure script checks the system hardware, and if the path variables are not set, asks for software paths to the W3 and BACIO libraries. It concludes by asking the user to choose a configuration supported by current machine architecture.

For Linux, there are six options:

1. Linux x86_64, PGI compiler (serial)
2. Linux x86_64, Intel compiler (serial)
3. Linux x86_64, Intel compiler super debug (serial)
4. Linux x86_64, PGI compiler, SGI MPT (serial)
5. Linux x86_64, Intel compiler, SGI MPT (serial)
6. Linux x86_64, Intel compiler, IBM POE (serial)

The configure script creates a file called `configure.trk`. This file contains compilation options, rules, and paths specific to the current machine architecture.

The configure file can be edited to change compilation options, if desired.

Compile the vortex tracker and save the build output to a log file:

`./compile |& tee tracker.log`

The command for the ksh/bash shell follows:

`./compile 2>&1 | tee tracker.log`

If the compilation was successful, three executables are created in the directory `trk_exec/`.

`hwrf_gettrk.exe`
`hwrf_tave.exe`
`hwrf_vint.exe`

If a recompilation is necessary, a clean to remove all object files should be completed:

`./clean`

A complete clean is strongly recommended if the compilation failed, the configuration file has been changed, or the configuration file is changed. To conduct a complete clean that
removes all built files in all directories, as well as the configure.trk, use the "-a" option:

./clean -a

2.10 Building the NCEP Coupler

2.10.1 Configure and Compile

Configure the NCEP Coupler for compilation from within the ncep-coupler/ directory:

./configure

The configure script checks the system hardware, asks the user to choose a configuration supported by current machine architecture, and creates a configure file called configure.cpl.

There are five dmpar options for Linux:

1. Linux x86_64, PGI compiler (dmpar)
2. Linux x86_64, PGI compiler, SGI MPT (dmpar)
3. Linux x86_64, Intel compiler (dmpar)
4. Linux x86_64, Intel compiler, SGI MPT (dmpar)
5. Linux x86_64, Intel compiler, IBM POE (dmpar)

The configure file configure.cpl contains compilation options, rules, and paths specific to the current machine architecture, and can be edited to change compilation options if desired.

Compile the coupler and save the build output to a log file.

./compile & tee coupler.log

For the ksh/bash shell, use the following command:

./compile 2>&1 | tee coupler.log

If the compilation is successful, it will create the single executable hwrf_wm3c.exe in the cpl_exec/ directory.

If a recompilation is necessary, a clean to remove all object files should be completed:

./clean

A complete clean is strongly recommended if the compilation failed, the configuration file has been changed, or the configuration file is changed. To conduct a complete clean that removes all built files in all directories, as well as the configure.cpl, use the "-a" option:
2. Software Installation

2.11 Building WPS

2.11.1 Set Environment Variables

The WRF WPS requires the same build environment as the WRF-NMM model, including the netCDF libraries and MPI libraries. Since the WPS makes direct calls to the WRF I/O API libraries included with the WRF model, the WRF-NMM model must be built prior to building the WPS.

Set up the build environment for WPS by setting the `WRF_DIR` environment variable:

```
setenv WRF_DIR ${SCRATCH}/hwrfrun/sorc/WRFV3/
```

For bash/ksh, use the command that follows:

```
export WRF_DIR=${SCRATCH}/hwrfrun/sorc/WRFV3/
```

Further details on using the WPS to create HWRF input data can be found in Chapter 4 of the HWRF Users’ Guide.

Complete details on building and running the WPS are available from the WRF-NMM Users’ Guide, and can be downloaded from:

```
```

2.11.2 Configure and Compile

Following the compilation of the WRF-NMM executables, change to the WPS directory and issue the configure command:

```
./configure
```

Select the appropriate `dmpar` option for your architecture and compiler choice. If you plan to use GRIB2 data, you will also need to select a build option that supports GRIB2 I/O. This will generate the configure resource file.

On Linux computers, there are 40 listed options. The first 28 are the most relevant to HWRF, and are listed below. Select a "NO_GRIB2" option if you do not want GRIB2 support:

1. Linux x86_64, gfortran (serial)
2. Linux x86_64, gfortran (serial_NO_GRIB2)
3. Linux x86_64, gfortran (dmpar)
2. Software Installation

4. Linux x86_64, gfortran (dmpar_NO_GRIB2)
5. Linux x86_64, PGI compiler (serial)
6. Linux x86_64, PGI compiler (serial_NO_GRIB2)
7. Linux x86_64, PGI compiler (dmpar)
8. Linux x86_64, PGI compiler (dmpar_NO_GRIB2)
9. Linux x86_64, PGI compiler, SGI MPT (serial)
10. Linux x86_64, PGI compiler, SGI MPT (serial_NO_GRIB2)
11. Linux x86_64, PGI compiler, SGI MPT (dmpar)
12. Linux x86_64, PGI compiler, SGI MPT (dmpar_NO_GRIB2)
13. Linux x86_64, IA64 and Opteron (serial)
14. Linux x86_64, IA64 and Opteron (serial_NO_GRIB2)
15. Linux x86_64, IA64 and Opteron (dmpar)
16. Linux x86_64, IA64 and Opteron (dmpar_NO_GRIB2)
17. Linux x86_64, Intel compiler (serial)
18. Linux x86_64, Intel compiler (serial_NO_GRIB2)
19. Linux x86_64, Intel compiler (dmpar)
20. Linux x86_64, Intel compiler (dmpar_NO_GRIB2)
21. Linux x86_64, Intel compiler, SGI MPT (serial)
22. Linux x86_64, Intel compiler, SGI MPT (serial_NO_GRIB2)
23. Linux x86_64, Intel compiler, SGI MPT (dmpar)
24. Linux x86_64, Intel compiler, SGI MPT (dmpar_NO_GRIB2)
25. Linux x86_64, Intel compiler, IBM POE (serial)
26. Linux x86_64, Intel compiler, IBM POE (serial_NO_GRIB2)
27. Linux x86_64, Intel compiler, IBM POE (dmpar)
28. Linux x86_64, Intel compiler, IBM POE (dmpar_NO_GRIB2)

Select the appropriate dmpar option for your choice of compiler.

Compile the coupler and save the build output to a log file:

    ./compile & tee wps.log

For the ksh/bash shell, use the equivalent command:

    ./compile 2>&1 | tee wps.log

After issuing the compile command, a successful compilation of WPS produces the three symbolic links: geogrid.exe, ungrib.exe, and metgrid.exe in the WPSV3/ directory, and several symbolic links in the util/ directory:

avg_tsfc.exe
calc_ecmwf_p.exe
g1print.exe
g2print.exe
height_ukmo.exe
int2nc.exe
mod_levs.exe
rd_intermediate.exe
If any of these links do not exist, check the compilation log file to determine what went wrong.

A complete clean is strongly recommended if the compilation failed or if the configuration file is changed. To conduct a complete clean that removes ALL build files, including the executables, libraries, and the `configure.wps`, use the "-a" option to clean:

```
./clean -a
```

For full details on the operation of WPS, see the WPS chapter of the WRF-NMM Users’ Guide.

### 2.12 Building UPP

The NCEP Unified Post-Processor was designed to interpolate WRF output from native coordinates and variables to coordinates and variables more useful for analysis. Specifically, UPP destaggers the HWRF output, interpolates the data from its native vertical grid to standard levels, and creates additional diagnostic variables.

The UPP requires the same Fortran and C compilers used to build the WRF model. In addition, UPP requires the netCDF library and the WRF I/O API libraries (the latter is included with the WRF build). The UPP build requires a number of support libraries (IP, SP, W3), which are provided with the source code and are located in the `UPP/lib/` directory. These libraries are for the UPP build only. They should not be confused with the libraries of the same name located in the `hwrf-utilities/libs/` directory.

#### 2.12.1 Set Environment Variables

The UPP requires the WRF I/O API libraries to successfully build. These are created when the WRF model is built. If the WRF model has not yet been compiled, it must first be built before compiling UPP.

Since the UPP build requires linking to the WRF-NMM I/O API libraries, it must be able to find the WRF directory. The UPP build uses the `WRF_DIR` environment variable to define the path to WRF. The path variable `WRF_DIR` must therefore be set to the location of the WRF directory.

In addition to setting the path variable, building UPP for use with HWRF requires setting the environment variable `HWRF`. This is the same variable set when building WRF-NMM for HWRF.

Set up the environment for UPP:
2. Software Installation

```bash
setenv HWRF 1
setenv WRF_DIR ${SCRATCH}/hwrfrun/sorc/WRFV3/
setenv JASPERLIB SYSTEM_LOCATION_SO_FILE
setenv JASPERINC SYSTEM_LOCATION_HEADER_FILE
```

The syntax for bash/ksh is as follows:

```bash
export HWRF=1
export WRF_DIR=${SCRATCH}/hwrfrun/sorc/WRFV3/
export JASPERLIB=SYSTEM_LOCATION_SO_FILE
export JASPERINC=SYSTEM_LOCATION_HEADER_FILE
```

### 2.12.2 Configure and Compile

UPP uses a build mechanism similar to that used by the WRF model. Within the UPP directory type:

```bash
./configure
```

to generate the UPP configure file. The configure script will complain if the WRF_DIR path has not been set. You will then be given a list of configuration choices tailored to your computer.

For the LINUX operating systems, there are 10 options. Select the appropriate `dmpar` option compatible with your system:

1. Linux x86_64, PGI compiler (serial)
2. Linux x86_64, PGI compiler (dmpar)
3. Linux x86_64, Intel compiler (serial)
4. Linux x86_64, Intel compiler (dmpar)
5. Linux x86_64, Intel compiler, SGI MPT (serial)
6. Linux x86_64, Intel compiler, SGI MPT (dmpar)
7. Linux x86_64, gfortran compiler (serial)
8. Linux x86_64, gfortran compiler (dmpar)
9. Linux x86_64, Intel compiler, IBM POE (serial)
10. Linux x86_64, Intel compiler, IBM POE (dmpar)

The configuration script will generate the `configure` file `configure.upp`. If necessary, the `configure.upp` file can be modified to change the default compile options and paths.

**NOTE:** When using PGI compilers, please edit `configure.upp` and remove the `-Ktrap` flags from `FFLAGS`.

To compile UPP, enter the following command (csh/tcsh):

```bash
./compile |& tee build.log
```

Alternatively, the ksh/bash command can be used:
2. Software Installation

`./compile 2>&1 | tee build.log`

This command should create 13 UPP libraries in `lib/`:

```
libbacio.a libsfcio.a
libCRTM.a libsgio.a
libg2.a libsp.a
libg2tmpl.a libw3emc.a
libgfsio.a libw3nco.a
libip.a libxmlparse.a
libnemsio.a
```

Four UPP executables are produced in `bin/`:

```
cnvgrib.exe
copygb.exe
ndate.exe
unipost.exe
```

Once again, these libraries are for the UPP only, and should not be used by the other components.

A complete clean is strongly recommended if the compilation failed, or if the configuration file or source code is changed. Conduct a complete clean that removes ALL build files, including the executables, libraries, and the `configure.upp`:

`./clean`

For full details on the operation of UPP, see the HWRF Post-Processor chapter of the HWRF Users’ Guide, and for complete details on building and running the UPP, see the UPP Users’ Guide, which can be downloaded at:

### 2.13 Building GSI

The community GSI requires the same build environment as the WRF-NMM model, including the netCDF, MPI, and LAPACK libraries. In addition, GSI makes direct calls to the WRF I/O API libraries included with the WRF model. Therefore the WRF model must be built prior to building the GSI.

Further details on using the GSI with HWRF can be found in later chapters of this HWRF Users’ Guide.
2. Software Installation

2.13.1 Set Environment Variables

Building GSI for use with HWRF requires setting three environmental variables. The first, HWRF, indicates to turn on the HWRF options in the GSI build. This is the same flag set when building WRF-NMM for HWRF. The second is a path variable pointing to the root of the WRF build directory. The third is the variable LAPACK_PATH, which indicates the location of the LAPACK library on your system.

Set up the environment for GSI:

```
setenv HWRF 1
setenv WRF_DIR ${SCRATCH}/hwrfrun/sorc/WRFV3/
```

You may use bash/ksh instead:

```
export HWRF=1
export WRF_DIR=${SCRATCH}/hwrfrun/sorc/WRFV3/
```

The additional environment variable LAPACK_PATH may be needed on some systems. Typically, the environment variable LAPACK_PATH needs only to be set on Linux systems without a vender-provided version of LAPACK. IBM systems usually have the ESSL library installed and therefore do not need the LAPACK. Likewise, the PGI compiler often comes with a vender-provided version of LAPACK that links automatically with the compiler. Problems with the vender-supplied LAPACK library are more likely to occur with the Intel compiler. While the Intel compilers typically have the MKL libraries installed, the ifort compiler does not automatically load the library. It is therefore necessary to set the LAPACK_PATH variable to the location of the MKL libraries when using the Intel compiler.

Supposing that the MKL library path is set to the environment variable MKL, then the LAPACK environment may be set in terms of MKL:

```
setenv LAPACK_PATH $MKL
```

Alternatively, the bash/ksh option is as follows:

```
export LAPACK_PATH=$MKL
```

2.13.2 Configure and Compile

To build GSI for HWRF, change into the GSI directory and issue the configure command:

```
./configure
```

Choose one of the configure options listed. On Linux computers, the listed options are as follows:

1. Linux x86_64, PGI compilers (pgf90 & pgcc) {dmpar, optimize}
2. Software Installation

2. Linux x86_64, PGI compilers (pgf90 & gcc) (dmpar, optimize)
3. Linux x86_64, GNU compilers (gfortran & gcc) (dmpar, optimize)
4. Linux x86_64, Intel compiler (ifort & gcc) (dmpar, optimize)
5. Linux x86_64, Intel compiler (ifort & icc) (dmpar, optimize)
6. Linux x86_64, Intel compiler (ifort & icc), IBM POE (EXPERIMENTAL) (dmpar, optimize)
7. Linux x86_64, Intel compiler (ifort & icc), SGI MPT (EXPERIMENTAL) (dmpar, optimize)

Select the appropriate dmpar option for your platform and compiler. For a generic Linux machine, choose option (1) or (2) for a PGI build, or option (4) or (5) for an Intel build.

After selecting the proper option, run the compile script:

```
./compile |& tee build.log
```

For the ksh/bash shell, use the following command:

```
./compile 2>&1 | tee build.log
```

The successful completion of the compile will place the GSI executable gsi.exe in the run/ directory. If the executable is not found, check the compilation log file to determine what went wrong.

A complete clean is strongly recommended if the compilation failed or if the configuration file is changed. To conduct a complete clean that removes ALL build files, including the executables, libraries, and the configure.gsi, use the "-a" option with clean:

```
./clean -a
```

For details on using GSI with HWRF, see the GSI chapter in the HWRF Users’ Guide. For full details on the operation of GSI, see the DTC Community GSI Users’ Guide:

http://www.dtccenter.org/com-GSI/users/docs/index.php
3.1 HWRF Scripts Overview

HWRF v3.7a is run by a series of high-level shell scripts in the wrappers/ directory, whose primary duty is to set environment variables and call the mid-level Python scripts in the scripts/ directory. The mid-level Python scripts call HWRF-specific Python modules in the ush/ directory and subdirectories. Many of the experiment configuration parameters and variables are set by files in the parm/ directory:

```
hwfrun/
  confdoc.py
  doc/
  exec/
  graphics/
  nwport/
  parm/
  README.md
  scripts/
  sorc/
  ush/
    hwrf/
    pom/
    produtil/
    hwrf_* .py
    hwrf_* .sh
    rocoto_* .sh
    rocoto_* .py
```
3. Running HWRF

The `doc` directory contains Doxygen based documentation about the scripting system. Please refer to http://www.dtcenter.org/HurrWRF/users/docs/index.php to access the documentation.

3.2 Defining an Experiment

3.2.1 Standard Configuration Files

The configuration of an HWRF experiment is controlled through the use of the configuration (*.conf) files in the `parm/` directory. Each of these configuration files has sections with headers contained in square brackets, e.g., `[config]`, `[dir]`, etc. Within a section, related variables are set.

There are four configuration files that are required by HWRF, and set all of the required variables needed to run every component of the workflow in the default configuration, which is the AL operational configuration. These four files are listed below:

```
hwrf.conf
hwrf_basic.conf
hwrf_input.conf
system.conf
```

The HWRF launcher, which is the first step in running HWRF, gathers all the options for a particular user configuration into the single file `storm1.conf` in the `${COMlwrf}` directory. It does this by first reading in the configuration variables in the four files listed above, then accepting as command line arguments to the script `exhwrf_launch.py` additional configuration files and variables. The last option passed to the launcher overrides any previous settings, except for when `basin_overrides=yes` (more on that later). When the user passes a variable on the command line, the section and variable name are required, e.g., `config.diskproject=dtc-hwrf`.

We recommend that users not edit the four main configuration files, but instead pass in their own configuration files and variables when running the HWRF launcher, which will override the default settings. Most of the variables are documented within the four main configuration files.
For the HWRF v3.7a public release, there is a fifth configuration file, hwrf_v3.7release.conf, which sets configuration options that require changes by the user, or that are required to be set based on the capabilities of HWRF v3.7a. The relevant variables are explained below.

[config]

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disk_project</td>
<td>User’s project on the computational platform.</td>
</tr>
<tr>
<td>input_catalog</td>
<td>Section within any configuration file that includes information about the locations and names of the input files. Community users should set it to comm_hist, which is defined below:</td>
</tr>
<tr>
<td>run_ensemble_da</td>
<td>Generates regional ensemble for data assimilation. This must be set to no because this capability is not supported in HWRFv3.7a.</td>
</tr>
<tr>
<td>scrub</td>
<td>Sets the automatic removal of temporary files.</td>
</tr>
</tbody>
</table>

[dir]

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputroot</td>
<td>Sets the path to the top-level data directory.</td>
</tr>
<tr>
<td>syndat</td>
<td>Sets the path to the input TC Vitals. Community users should set it to the location of staged SYNDAT–PLUS dataset, as explained later in this chapter.</td>
</tr>
<tr>
<td>outputroot</td>
<td>Sets the desired location of parent output directory.</td>
</tr>
<tr>
<td>CDNOSCRUB</td>
<td>Sets the path to the saved output.</td>
</tr>
<tr>
<td>CDSCRUB</td>
<td>Sets the path to the top-level output. Files and directories contained within would be scrubbed in the operational workflow by default to save disk space.</td>
</tr>
<tr>
<td>CDSAVE</td>
<td>Sets the path to the parent of the hwrfrun directory.</td>
</tr>
</tbody>
</table>

Other Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrub</td>
<td>Sets the automatic removal of temporary files in [relocate], [gsi_d02], and [gsi_d03] working directories.</td>
</tr>
</tbody>
</table>

To turn off scrubbing for any component of HWRF, set scrub=no for that section of configuration, e.g. pass relocate.scrub=no to the exhwrf_launch.py script.

The [comm_hist] section provides the directory structure and naming conventions for the input data, where inputroot defines the parent data directory path.

The [exe] section provides the paths to the compiled executables.
3. Running HWRF

Overview of hwrf.conf

The variables contained in hwrf.conf primarily define namelist options for the components of HWRF. Please refer to the descriptions of the variables within the hwrf.conf, along with the WRF NMM Users’ Guide. Also included in this file is the mapping to the executables used in operations, which differ only by location from the executables used in the public release (overridden by hwrf_v3.7release.conf).

Overview of hwrf_basic.conf

The variables that are found in hwrf_basic.conf define the HWRF workflow configuration. Users should be familiar with a few of the relevant sections and variables within this file, as follows. Further discussion about the use of these options is saved for section 3.6.

```
[config]
forecast_length  Length of atmospheric forecast. Default is 126 hours.
run_gsi          Option to run GSI and FGAT initialization.
run_ocean        Option to run POM coupling.
run_relocation   Option to run vortex relocation/initialization.
run_ensemble_da  Option to run the DA ensemble (not supported in v3.7a).
run_satpost      Option to make synthetic satellite products.
use_spectral     Option to use spectral global files as input to prep_hybrid.
                  If no, GRIB input files are used. Note that the GSI still needs spectral input from GDAS and the GFS Ensemble to run in hybrid mode.
spectral_bdy     Option to use spectral global files as boundary conditions if use_spectral=yes. If no, GRIB input files are used
extra_trackers   Option to run the GFDL vortex tracker on d02 and d03 (not supported in v3.7a).
```

Another important variable in this configuration file is allow_fallbacks. Most community users will have it set to no, which is the default. In operations, this variable is set to yes, which enables alternate paths in the HWRF run in case a component fails. For instance, when allow_fallbacks is set to yes and GSI fails, the run does not stop but instead the initial conditions for the main forecast are obtained directly from the output of the vortex relocation.

```
[prelaunch]
The variable basin_overrides is perhaps the most powerful of all the variables in the configuration files. This variable, when set to yes, will cause HWRF to run with operational settings for each basin by automatically loading a configuration file for a particular basin. Command line arguments to exhwrf_launch.py will not override the settings within the basin-specific configuration files. Operational settings for each basin, along with the corresponding configuration files, are described in table 3.1.
```

```
[sanity]
```

Table 3.1: Default settings for each basins.

Variables in this section control which checks run during the execution of launcher_wrapper.

[dir]
Contains variables that build paths based on the paths provided by CDSAVE, CDSCRUB, CDNOSCRUB, and EXPT. These variables should be changed with extreme caution. Following is a description of three of the most important [dir] variables:

- **WORKhwrf**: The working directory for all jobs. These directories are scrubbed in the operational workflow to save disk space.
- **HOMEhwrf**: HWRF installation location.
- **com**: Location of output files for delivery to operational centers or for use by the next HWRF cycle.

### Overview of hwrf_input.conf

This file defines the input data directory structure. It currently contains input data locations for users on the NOAA research and development machines Zeus or Jet with access to the EMC input data directory, and for community users that stage the input data using the directory structure described in section 3.3. These three sets of input data are described in the sections labeled [zeus_hist], [jet_hist], and [comm_hist], respectively. Settings for [comm_hist] for this release can be found in hwrf_v3.7release.conf.

Users who wish to adopt a different input data directory structure may define it within this
3. Running HWRF

file by adding an additional section, or by editing the existing [comm_hist] section. While
the input data can be placed anywhere that is locally available to the compute nodes, users
are not advised to change the input file naming convention.

The choice of which set of input data will actually be used in an experiment is determined
by variable input_catalog in file system.conf. To use the test datasets provided by
DTC, users should set this variable to comm_hist. The user must also set the path to the
location of the input data within the [comm_hist] section of hwrf_input.py by editing
the variable inputroot.

Overview of system.conf

This file defines the top-level output directory structure and a handful of other variables
used for running HWRF. Community users need to copy or link the example file sys-
tem.conf.jet to system.conf. The following variables are user-dependent and originate
from this file, but should be set in hwrf_v3.7arelease.conf.

disk_project    Project on the computational platform (used to compose
                the output directory name).
input_sources    Variable that sets the configuration section that defines
                the local and remote staging areas of input data. This
                configuration section must exist in one of the config-
                uration files used by HWRF (i.e., hwrf_input.conf,
                hwrf_v3.7arelease.conf, etc.). Community users
                should set it to comm_hist.
input_catalog    Variable that sets the configuration section that defines
                the input file location. This section must exist in one of
                the configuration files used by HWRF. Community users
                should set it to comm_hist.
[dir] section    CDNOSCRUB, CDSCRUB, and CDSAVE set the location of
                the HWRF install and output files.
syndat           The path to input TC Vitals. Community users should set
                it to the path for the staged SYNDAT–PLUS dataset, as
                explained later in this chapter.

The sections [wrfexe] and [runwrf] describe the mapping of the processor distribution
for the WRF runs and should not be altered.

3.3 Input Data and Fix Directory Structure

Users will need the datasets below as input to HWRF components.

The following lists outline the files needed to initialize forecast using the operational
configuration. Analysis times are indicated by capital letters, such as YYYYMMDDHH
or HH, and forecast hours are indicated by lowercase letters, i.e., hhh. For example,
3. Running HWRF

gfs.2012102806.pgrbf024 is a GFS 24-h forecast in GRIB format whose initial time is October 28 06Z 2012 and would be indicated as gfs.YYYYMMDDHH.pgrbfhhh. The storm identifier, *sid* is the storm number and a lower-case letter corresponding to the basin (e.g., 08l).

```
./
  DATA/.................................................. Top level data directory
  gfs.YYYYMMDDHH/
  enkf.YYYYMMDDHH/
  loop/
  recon.YYYYMMDDHH/
  gdas1.YYYYMMDD/
  SYNDAT-PLUS/
    _tcvitals.txt.prev.YYYY
    syndat_tcvitals.YYYY
    _investnamed/
    _old/
    _renumbered/
    _work/
  tdr.YYYYMMDDHH/ ..................... TDR data, if available
  fix/
    _bogus/
    _hwrf_cpat.ice
    _hwrf_cpat.moddef
    _hwrf_cpat.wind
    _hwrf-crtm-2.0.6/.............. Updated Coefficients for Radiative Transfer
    _hwrf-crtm-2.2.0/.............. Updated Coefficients for Radiative Transfer
    _hwrf-crtm-2.2.1/.............. Updated Coefficients for Radiative Transfer
    _hwrf_disclaimer.txt
    _hwrf_eta_micro_lookup.dat
    _hwrf_fix_datestamp
    _hwrf-pom/............................. Ocean init climate data
    _hwrf_storm_20
    _hwrf_storm_25
    _hwrf_storm_cyn_axisy_47
    _hwrf_storm_cyn_axisy_50_ep
    _hwrf_storm_radius
    _hwrf_track
    _hwrf_wps_geo/..................... Land use fixed files
    _hwrf-wrf/............................. Fixed files for WRF
  loop_curr/.......................... Loop current initialization data
```

The loop/ directory contains loop current and warm core ring initialization data in the following two files.

- gfdl_loop_current_rmy5.dat.YYYYMMDD Loop current data
- gfdl_loop_current_wc_ring_rmy5.dat.YYYYMMDD Warm core ring data

The gfs.YYYYMMDDHH/ directory contains spectral atmospheric analyses.
3. Running HWRF

`gfs.tHH.sanl` GFS analysis for ocean initialization
`gfs.tHH.sfcanl` GFS sfc analysis for ocean initialization
`gfs.tHH.sfhhh` GFS analysis for atmospheric initialization (0 to 126h in 3 h increments)

The `gfs.YYYYMMDDHH/` directory also contains data for the initialization of the atmosphere. These fall into three categories: observations, gridded data, and spectral data. The prefix for each file denotes the numerical weather prediction (NWP) system from which the data originate.

The following files are considered observations, and are in either BUFR or prepBURF formats where `HH` is the analysis time:

- `gfs.tHH.prepbufr.nr` Conventional obs
- `gfs.tHH.SATELLITE.tm00.bufr_d` Satellite obs

In the list above, SATELLITE can be any of the following, but this is not an all-inclusive list:

- `1bamua`
- `1bamub`
- `1bhrs3`
- `1bhrs4`
- `1bmhs`
- `airsev`
- `ascatt`
- `ascatw`
- `atms`
- `avcsam`
- `avcspm`
- `cris`
- `esamua`
- `esamub`
- `goesfv`
- `gome`
- `gpsro`
- `mtiasi`
- `rassda`
- `sevcsr`
- `satwind`

The following file is in gridded binary (GRIB) format:

- `gfs.tHH.pgrb2.0p25.f00` GFS analysis

The `enkf.YYYYMMDDHH/` directory contains the GFS Ensemble spectral data used for data assimilation. There are eighty files named

`sfg_YYYYMMDDHH_fhrhhs_mem{mmm}`, where `mmm` is the 3-digit ensemble member ID, which ranges from 001 to 080.

The `gdas1.YYYYMMDDHH/` directory contains the GDAS files to provide first guess information for data assimilation.

The following files are in gridded binary (GRIB) format:

- `gdas1.tHH.pgrb2.1p00.f003` 3-h forecast from previous 6-h GDAS cycle
- `gdas1.tHH.pgrb2.1p00.f006` 6-h forecast from previous 6-h GDAS cycle
- `gdas1.tHH.pgrb2.1p00.f009` 9-h forecast from previous 6-h GDAS cycle

The following files are considered observations, and are in either BUFR or prepBURF formats. `HH` is the analysis time and `HH-6` is the analysis time six hours prior.

- `gdas1.t(HH-6).abias` Time-dep. sat. bias correction
- `gdas1.t(HH-6).abias_pc` Satellite-bias correction coefficients
The remainder of the files are spectral files in binary format.

- `gdas1.tHH-6.sf03` 3-h forecast from previous 6-h GDAS analysis
- `gdas1.tHH-6.sf06` 6-h forecast from previous 6-h GDAS analysis
- `gdas1.tHH-6.sf09` 9-h forecast from previous 6-h GDAS analysis

The `SYNDAT-PLUS` directory contains the TC Vitals files for several years.

The `recon.YYYYMMDD` directory contains aircraft reconnaissance data in BUFR format and some additional files with metadata. Files are named by the following conventions:

- `gdas1.tHH.SID.hdobs.tm00.bufr_d`

The `tdr.SID/YYYY/YYYYMMDDHH/SID` directory contains TDR data in BUFR format in a file named as follows:

- `gdas1.tHHz.tldplr.tm00.bufr_d`

The fix files are time-independent and are included in the following directories:

- **bogus/**
  - `hwrfofs_at1.A12grid.dat`
  - `hwrfofs_at1.intp_pars.dat`
  - `hwrfofs_atl.ismus_msk1152x576.dat`
  - `hwrfofs_atl.ismus_msk384x190.dat`
  - `hwrfofs_atl.ismus_msk512x256.dat`
  - `hwrfofs_atl.ismus_msk768x384.dat`
  - `hwrfofs_atl.ncep1_12.regional.depth.a`
  - `hwrfofs_atl.ncep1_12.regional.depth.b`
  - `hwrfofs_atl.ncep1_12.regional.grid.a`
  - `hwrfofs_atl.ncep1_12.regional.grid.b`
  - `hwrfofs_atl.ncep1_12.regional.mask.a`
  - `hwrfofs_atl.ncep1_12.regional.mask.b`

- **hwrfcrtm-2.2.1/**
  - `AerosolCoeff/
  CloudCoeff/
  EmisCoeff/
  SpcCoeff/
  TauCoeff/

- **hwrfgsi/** Note: starting with v3.7a, the GSI fixed files are included in the sor-c/GSI/fix directory
  - `anavinfo_hwrfl60`
  - `anavinfo_hwrfl60_nooz`
  - `anavinfo_hwrfl75`
  - `atms_beamwidth.txt`
  - `bufrtab.012`
  - `global_ozinfo.txt`
  - `global_scaninfo.txt`
  - `hwrf_convinfo.txt`
3. Running HWRF

46
3. Running HWRF

hwrf_gfdl_loop_current_wc_ring_rmy5.dat.

Sample fix files and datasets for running two consecutive forecasts of Hurricane Gonzalo (October 14, 2014 12 and 18 UTC) can be obtained from the DTC website: http://www.dtcenter.org/HurrWRF/users. To use the DTC-supported scripts for running HWRF, these datasets should be stored following the directory structure described above, and must be on a disk accessible by the HWRF scripts and executables.

The following files are available for download:

- HWRF_v3.7a_datasets_enkf.2014101406.tar.gz
- HWRF_v3.7a_datasets_enkf.2014101412.tar.gz
- HWRF_v3.7a_datasets_gfs.2014101412.tar.gz
- HWRF_v3.7a_datasets_gdas.2014101412.tar.gz
- HWRF_v3.7a_datasets_recon.tar.gz
- HWRF_v3.7a_datasets_SYNDAT-PLUS.tar.gz
- HWRF_v3.7a_datasets_loop.tar.gz
- HWRF_v3.7a_fix.tar.gz

3.4 Production Directory Structure

The top production directory is ${WORKhwrf}/YYYYMMDDHH/SID (where ${WORKhwrf} is an environment variable defined by the scripts, SID is storm ID (e.g., 09L), and YYYYMMDDHH is the forecast initial time. The following subdirectories will be present for the default AL configuration.

```
${WORKhwrf}/YYYYMMDDHH/SID
    ├── cpl.out
    │     └── Coupler std out
    ├── fgat.YYYYMMDDHHHH/.................................................. Production dir for processing GDAS at each of the fgat hours: -3, 0 +3
    └── gfsinit/................................................................. Production dir for processing GFS input
        ├── ghost/
        │    └── Production dir for processing GDAS at each of the fgat hours: -3, 0 +3
        ├── prep_hybrid/

        └── tracker/
            └── Production dir for processing GDAS at each of the fgat hours: -3, 0 +3
        └── wps/
            └── Production dir for processing GDAS at each of the fgat hours: -3, 0 +3
            └── wrfanl/
                └── Production dir for processing GDAS at each of the fgat hours: -3, 0 +3
        └── gsi_d02/.............................................................. Production dir for data assimilation on 6 km domain
            └── gsi_d03/.............................................................. Production dir for data assimilation on 2 km domain
                └── hwrf_state.sqlite3............................................ Datastore file
                    └── hwrf_state.sqlite3.lock
```
3. Running HWRF

- **intercom/**: Dir containing files needed for subsequent processes
- **lock/**: Datastore directory
- **oldvit/**: Previous 6 h Tcvitals
- **pom/**: Production dir for the ocean initialization
- **regridger/**: Working dir for regribbing process. All files are delivered to other locations
- **regridger-[0003-0010].out/**: Standard output from regribber
- **regridger-[0003-0010].err/**: Standard error from regribber
- **runwrf/**: Production dir for coupled or uncoupled forecast
- **storm1.vitals/**: Text file containing TC Vitals for forecast storm, including only the current storm label, i.e., 08L for Gonzalo
- **storm1.vitals.allids/**: Text file containing TC Vitals for forecast storm, including its Invest labels, i.e., 99L and 08L for Gonzalo
- **storm1.vitals.oldid/**: Text file containing TC Vitals for forecast storm, including only its Invest labels, i.e., 99L for Gonzalo
- **storm1.vitals.renumberlog/**: Log file for vitals messages processed
- **tmpvit/**: Text file containing only the analysis TC Vital message
- **tracker/**: Production dir for the GFDL Vortex Tracker
- **trackerd01/**: Production dir for the GFDL Vortex Tracker from parent domain
- **trackerd02/**: Production dir for the GFDL Vortex Tracker from d02 domain
- **tracker-[0000-0003].out/**: Standard output from tracker

The purpose of `intercom/` is to store the files that are used for subsequent processes, separating them from the working directory. Within the `intercom/` directory, the structure is similar to that in the `${WORKhwrf}` directory, except each subdirectory contains only the files that will be used in subsequent steps. The following outlines the structure of `intercom/` when running all components of HWRF as in the default AL configuration.

```
intercom/
|__ bufrprep/
|  |__ fgat.tYYYYMDDHHHHH/

|  |__ satpost-fhh00m-stormlouter.egrb
```

48
3. Running HWRF

Additionally, some output files are transferred to the `com/` directory, which is reserved for transfer of files between cycles and for delivery of final products (in an operational setting). This is discussed in Chapter 11.

In the list above, date strings will be substituted for each forecast hour or `fgat` time. `GRID` denotes grids of various domains, e.g., d1, d123, d2, d23, d3, and grid spacings used for regribbing the HWRF forecast for delivery and product generation. In this context, `moad` stands for *Mother Of All Domains*, or the HWRF parent grid. Conversely, `outer` and `inner` refer to the intermediate and innermost nests. More information about each grid can be found in section 11.2.1.

3.5 Scripts for Running HWRF

We recommend that HWRF v3.7a be run using the wrapper and Python scripts provided with the HWRF v3.7a release. In `scripts/`, users can find mid-level Python scripts that call HWRF-specific Python utilities located in `ush/`. Users are encouraged to run the scripts in the `scripts/` directory using the wrapper scripts located in `wrappers/`. The wrapper scripts set the proper environment variables to run each Python script, as well as execute multiple iterations as needed.

3.5.1 Submitting a Job

Some of the executables are parallel code and can only run on the computation nodes. We recommend that users first connect to the computer’s remote computation nodes. To do this on Linux machines that run the MOAB/Torque, such as NOAA’s Jet, users can use the `qsub` command. For example, the command below requests a two-hour connection of 24 cores on the “sJet” nodes using the account “dtc-hurr”.

```
qsub -X -I -l procs=24,walltime=2:00:00,partition=sjet -A dtc-hurr
```

The user should seek assistance from the system administrator on how to connect to the computation nodes on the machine used to run HWRF.

Parallel code can also be submitted to the computation nodes using a batch system. For a platform that uses the batch system Load Sharing Facility (LSF), the beginning of each wrapper script should be edited to add the LSF options listed below:
#BSUB -P 99999999  # Project name
#BSUB -a poe      # Select poe
#BSUB -n 202      # Number of total (MPI) tasks
#BSUB -R "span[ptile=32]"  # Run a max of 16 tasks per node
#BSUB -J hwrf    # Job name
#BSUB -o hwrf.%J.out  # Standard output file name
#BSUB -e hwrf.%J.out # Standard error file name
#BSUB -W 2:30     # Wallclock time
#BSUB -q debug    # Queue name
#BSUB -K         # Don't return prompt until the job is finished

For a platform that uses the MOAB/Torque batch system, the beginning of each wrapper script should be edited to add the PBS options listed:

#PBS -A project  # Project name
#PBS -l procs=202 # Number of total (MPI) tasks
#PBS -o stdout.txt # Standard output file name
#PBS -e stderr.txt # Standard error file name
#PBS -N hwrf    # Job name
#PBS -l walltime=02:30:00 # Wallclock time
#PBS -q batch    # Queue name
#PBS -d .       # Working directory of the job

After the batch system options and environment variables are defined, run the wrapper scripts using the command:

- On machines with LSF:
  ```
  bsub sample_wrapper
  ```

- On machines with MOAB/Torque:
  ```
  qsub sample_wrapper
  ```

The wrapper script `sample_wrapper` will be submitted to the computation nodes and, once it starts, will call the low-level script from the `scripts/` directory. Appendix A contains the guidelines for resources used to run HWRF at near operational efficiency.

3.6 Running HWRF End-to-End

3.6.1 Editing global_vars.sh

The file `global_vars.ksh` is used for setting a few environment variables to define the cycle(s) to be run by the wrapper scripts. The user should set the first four variables. Variables are set for the Gonzalo example case provided by the DTC.
3. Running HWRF

export START_TIME=YYYYMMDDHH  
Initial time of the forecast
export SID=08L                
Storm ID, e.g. 08L is Gonzalo – the 08th
storm of the Atlantic season; Invest 99 in
the East Pacific would be 99E
export CASE=HISTORY           
For most users, this will be HISTORY. FORE-
CAST is reserved for real-time mode.
export HOMEhwrf=              
Full path to the directory where HWRF has
been installed, including /hwrf/run

3.6.2 Using Wrapper Scripts

Once all configure files and global_vars.sh have been edited to define an experiment,
the wrapper scripts should be submitted to the batch system. Some of the wrappers have
dependencies on previous wrappers, while others can be run simultaneously. The following
list contains all of the wrappers to be run for a default Atlantic Basin case. The items
under the same number can be submitted together in any order, but only after the previous
numbered item(s) runs to completion:

1. launcher_wrapper
2. init_gdas_wrapper
   init_gfs_wrapper
   init_ocean_wrapper
   bufrprep_wrapper
3. relocate_wrapper
4. gsi_d02_wrapper
   gsi_d03_wrapper
5. merge_wrapper
6. unpost_wrapper
7. forecast_wrapper
   post_wrapper†
   products_wrapper†

†Wrapper can run at the same time as forecast_wrapper, but should only be submitted
after the forecast job has started, i.e., no longer in queue.

Wrappers with the same number may be run sequentially or simultaneously. Because the
forecast job often waits in the queue before it starts, a post job submitted at the same time
as the forecast job will have nothing to do for quite a while and will use wallclock time
waiting on output from the forecast. Therefore, we suggest submitting the post and products
wrappers after the forecast job has started running.

By default, the launcher_wrapper reads in the configure files system.conf,
hwrf.conf, hwrf_input.conf, hwrf_v3.7release.conf and hwrf_basic.conf.
Additional variables and configure files can be passed to exhwrf_launcher.py within the
launcher_wrapper by following the syntax documented within the Python script. For
variables defined more than once, the variable will take the value that was last passed to
3. Running HWRF

exhwrf_launcher.py.

The configuration set by the user will determine the wrapper scripts that are required. Keep in mind, however, that when the variable basinoverrides=yes, the configuration changes based on the basin for which you are running, so wrappers should be submitted accordingly.

An example of the command used in the launcher_wrapper for running AL storm Gonzalo is as follows. Please refer to the documentation block of scripts/exhwrf_launch.py for complete argument list. The environment variables $HOMEhwrf, $EXPT, $CASE_ROOT, and $startfile are defined in global_vars.sh.

$HOMEhwrf/scripts/exhwrf_launch.py 2014101412 08L HISTORY
"$HOMEhwrf/parm" "config.EXPT=$EXPT" "config.startfile=$startfile"
"config.HOMEhwrf=$HOMEhwrf" "config.case_root=$CASE_ROOT"
"$HOMEhwrf/parm/hwrf_v3.7release.conf"

To run the full default AL configuration for any other basin, simply set prelaunch.basinoverrides=no as an additional argument in the previous example and choose the date and storm ID for a storm in a different basin.

In addition to editing the launcher_wrapper, the forecast_wrapper will also require the user to edit the number of processors, depending on the status of ocean coupling and resolution used for the forecast. Please refer to the comments within the forecast_wrapper for the appropriate choice of processors.

3.7 Operational HWRF in Each Ocean Basin

In the 2015 Operational implementation of HWRF, the configuration of the system varies by basin as described in table 3.1. The following sections describe the workflow of each of those configurations, and the appropriate wrappers to go with them.

3.7.1 Atlantic Basin

In Figure 3.1, each blue box corresponds to a component of HWRF that is run in the default configuration. Except for the forecast grouping, each box has its own corresponding wrapper. The three components of the forecast are run simultaneously by the forecast_wrapper. The bufrprep_wrapper and unpost_wrappers are preparation steps for the GSI and the post jobs, respectively, and are not shown as components in the figures.
3. Running HWRF

![Diagram of HWRF components]

Figure 3.1: Components of HWRF that run for the operational AL configuration.

### 3.7.2 Eastern Pacific Basin

In Figure 3.2, the workflow "With Inner Core Data" is used when TDR from a NOAA P3 flight is available. This configuration, which is quite rare given that flights do not often occur for EP storms, uses all of the same wrappers as the AL configuration. The bottom workflow of Fig. 3.2 describes the most common EP configuration.

Before running this workflow, users need to edit the `relocate_wrapper` to remove or comment the lines related to running vortex relocation on the GDAS files.

```bash
# Run the python relocate script for fgat times
# if test "$GSI" = "YES" ; then
# export INIT_MODEL=gdas1
# for fhr in 3 6 9 ; do
# export INIT_FHR=$fhr
# $EXhwrfexhwrf_relocate.py
# done
# fi
```

The wrappers below should be used when no TDR data is available for an EP storm.

1. `launcher_wrapper`
2. `init_gfs_wrapper`
3. `init_ocean_wrapper`
4. `relocate_wrapper`
5. `unpost_wrapper`
6. `forecast_wrapper`
7. `post_wrapper†`
8. `products_wrapper†`

†Wrapper can run at the same time as `forecast_wrapper`, but should only be submitted after the forecast job has started, i.e., no longer in queue.
3. Running HWRF

Figure 3.2: Components of HWRF that run for the operational EP configuration, which depends on the existence of inner core data.

3.7.3 All Other Basins

Beginning in 2015, HWRF is run operationally for all ocean basins globally. These include the North Central Pacific, North West Pacific, Northern Indian Ocean, South Pacific, Southern Indian Ocean, and Southern Atlantic Basins. While the configuration of the vertical levels differs between these basins, the workflow configuration does not. Notice in Fig. 3.3 that the workflow has been simplified a great deal. The only wrappers required to run the default cases for these basins are as follows:

1. launcher_wrapper
2. init_gfs_wrapper
3. relocate_wrapper
4. unpost_wrapper
5. forecast_wrapper
   post_wrapper†
   products_wrapper†

†Wrapper can run at the same time as forecast_wrapper, but should only be submitted after the forecast job has started, i.e., no longer in queue.

Note: Do not forget to edit the forecast_wrapper for an uncoupled run.
3. Running HWRF

Figure 3.3: Components of HWRF that run for the operational configuration in all other basins.

3.8 Running HWRF in Non-operational Configurations

Users may wish to run HWRF with a different set of components than those used in operations. Most alternate configurations will require the user to set `basin_overrides=no`. If `basin_overrides=no` is the only additional configuration option set, all runs in all basins will be configured as the AL default.

The basin-specific configuration files listed in the "Extra conf" column of table 3.1 may still be passed through the launcher, but the variables within can be overridden by a subsequent argument to `exhwrf_launch.py`.

The remainder of this section describes a few alternate options that are supported when using HWRF v3.7a. These examples are also included in `launcher_wrapper`. It is left to the user to choose combinations of the following configuration options.

3.8.1 Running Coupled/Uncoupled Forecast

Coupling with the ocean is enabled by default for the AL and EP basins. To run an uncoupled forecast (no ocean) in the AL or EP basins, set `config.run_ocean=no`.

This configuration option also requires a change in the number of processors in the `forecast_wrapper`. Please see the explanation contained in the comments section of the wrapper to set the appropriate number of processors.

To enable ocean in any other basin, the two arguments below should be passed to `exhwrf_launch.py`.

```
prelaunch.basin_overrides=no
run_ocean=yes
```

If the ocean is the only component to be changed, the `hwrf_other_basins.conf` must also be used explicitly in the `launcher_wrapper`, otherwise the default AL configuration
will be run.

An example of the arguments passed to `exhwrf_launch.py` within the `launcher_wrapper` to run an ocean-coupled forecast for a WP storm, retaining all other operational setting, follows:

```
$HOME/hwrf/scripts/exhwrf_launch.py 2014100906 19W HISTORY
"$HOME/hwrf/parm" "config.EXPT=$EXPT" "config.startfile=$startfile"
"config.HOMEhwrf=$HOMEhwrf" "config.case_root=$CASE_ROOT"
"$HOME/hwrf/parm/hwrf_v3.7release.conf" "prelaunch.basin_overrides=no"
"$HOME/hwrf/parm/hwrf_other_basins.conf" "config.run_ocean=yes"
```

Wrappers to be run for this example are the same as for the EP configuration without inner core data.

Alternatively, to run an uncoupled forecast with full AL configuration for any basin, pass the following arguments:

```
prelaunch.basin_overrides=no
run_ocean=no
```

Run this configuration with the following wrappers as shown in Fig 3.4:

1. launcher_wrapper
2. init_gdas_wrapper
   init_gfs_wrapper
   bufrprep_wrapper
3. relocate_wrapper
4. gsi_d02_wrapper
   gsi_d03_wrapper
5. merge_wrapper
6. unpost_wrapper
7. forecast_wrapper
   post_wrapper†
   products_wrapper†

†Wrapper can run at the same time as forecast_wrapper, but should only be submitted after the forecast job has started, i.e., no longer in queue.

Note: Do not forget to edit the forecast_wrapper for the appropriate number of processors.
3. Running HWRF

Figure 3.4: Components of HWRF that run for uncoupled configuration.

3.8.2 Running with Optional GSI

A user may choose to run with or without data assimilation in any given basin. To force HWRF to run with GSI in any basin while retaining the other operational settings, set the following variables:

- `prelaunch.basin_overrides=no`
- `run_gsi=yes`

Also pass the appropriate basin-specific configuration file listed in the "Extra conf" column of table 3.1 to `exhwrf_launch.py`.

To run without GSI in a full AL configuration for any basin, the following arguments should be passed to `exhwrf_launch.py`.

- `prelaunch.basin_overrides=no`
- `run_gsi=yes`

These arguments will set up the configuration shown in Fig. 3.5, and the following wrappers should be run:

1. `launcher_wrapper`
2. `init_gfs_wrapper`
   - `init_ocean_wrapper`
3. `relocate_wrapper`
4. `unpost_wrapper`
5. `forecast_wrapper`
   - `post_wrapper†`
   - `products_wrapper†`

†Wrapper can run at the same time as `forecast_wrapper`, but should only be submitted after the forecast job has started, i.e., no longer in queue.
3. Running HWRF

**Figure 3.5:** Components of HWRF that run with GSI turned off.

### 3.8.3 Running without Vortex Initialization

The HWRF scripts require vortex relocation to be run before data assimilation can be performed. A feature introduced in HWRF v3.7a allows users to turn off the vortex adjustment component of the vortex initialization, and allow for only vortex relocation. Both options require `config.run_relocate=yes`. The configuration variable `relocate.initopt` controls the initialization procedure and should be set to "0" for full vortex initialization, or "1" for relocation only. Pass the `relocate.initopt` option to `exhwrf_launch.py` to change the relocation behavior.

To turn vortex initialization off completely from the full AL configuration for any basin, data assimilation must also be turned off, and the following arguments must be passed to `exhwrf_launch.py`:

```
run_gsi=no
run_relocate=no
```

There is no need to turn off `prelaunch.basin_overrides` for this case.

This configuration corresponds to that shown in Fig. 3.6 and requires the following wrappers:

1. `launcher_wrapper`
2. `init_gfs_wrapper`
   - `init_ocean_wrapper`
3. `unpost_wrapper`
4. `forecast_wrapper`
   - `post_wrapper†`
   - `products_wrapper†`

†Wrapper can run at the same time as `forecast_wrapper`, but should only be submitted after the forecast job has started, i.e., no longer in queue.
3. Running HWRF

Figure 3.6: Components of HWRF that run without vortex initialization.

3.8.4 Running without Spectral Files (GRIB Only)

To run with GRIB input files only, the following arguments should be passed to `exh-wrf_launch.py`.

```
use_spectral=no
```

When running with GRIB files only, data assimilation needs to be disabled or used in 3DVAR-only mode (hybrid data assimilation is not supported since it depends on the ingesting the spectral ensemble files). Therefore, one of the following two options must be adopted when using `use_spectral=no`:

**No data assimilation:**

```
config.run_gsi=no
```

See section 3.8.2 for details on running these configurations.

**3DVAR data assimilation using the default AL configuration in any basin:**

```
preflight.basin_overrides=no
cfg.run_gsi=yes
gsi_d02_nml.HYBENS_REGIONAL=F
gsi_d03_nml.HYBENS_REGIONAL=F
```

Also set `gsi_d02.use_gfs_stratosphere=no` if you do not have GDAS forecast spectral files.

3.8.5 Running with 27/9/3-km Configuration

It is possible to run v3.7a with 27/9/3-km resolution, the resolution used in v3.5a (2013) and v3.6a (2014). The rest of the system will be the same. Table 3.2 shows the settings for 27/9/3-km configuration for all the ocean basins. Add the relevant configuration file to the arguments in `launcher_wrapper` and set `preflight.basin_overrides=no`.

Table 3.2: Settings for all basins with 27/9/3 km configuration.
3. Running HWRF

3.8.6 Running with 43 Vertical Levels

HWRF v3.7a runs with 43 vertical levels by default for basins other than AL, EP, and CP. To use this option for any configuration, pass `prelaunch.basin_overrides=no` and the `parm/hwrf_43lev.conf` as arguments to `exhwrf_launch.py`.

Note that if reduced horizontal resolution and vertical resolution to 27/9/3 km with 43 vertical levels is a desired configuration, `hwrf_3km.conf` must be passed after the `hwrf_43lev.conf` file.
HWRF Preprocessing System

4.1 Introduction

HWRF needs data from the operational GFS and GDAS for its initialization procedures. Ultimately, the GFS dataset is used to create initial and boundary conditions for the 18-km outer domain, while the GDAS dataset is used to initialize the inner 6- and 2-km domains. However, as we explain later, the GDAS analysis and forecast are also used in the 18-km domain for an intermediate step.

The GFS analysis and forecast employed are from the same cycle as the HWRF initialization (e.g., to initialize a HWRF forecast at 12 UTC, the 12 UTC run of GFS is used). However, the GDAS data used by HWRF are forecasts from the previous 6-h cycle (e.g., to initialize a HWRF forecast at 12 UTC, the forecasts from 06 UTC run of GDAS are used). This differentiation is related to the data assimilation procedures (Chapter 6). First of all, data assimilation in HWRF is only conducted in the inner 6- and 2-km domains. A forecast from the GDAS initialized 6-h before the HWRF analysis provides a better first guess than the GDAS analyses at the same initialization time as HWRF, in which observations have already been included as part of the global data assimilation procedures. Second, the HDAS ingests observations in a 3-h time window centered in the HWRF analysis time. This requires the availability of three first-guess files, one at the HWRF analysis time, one before and one after. By using the GDAS forecast initialized 6-h before the HWRF analysis, HWRF can make use of the GDAS 3-, 6-, and 9-h forecast lead times, which are valid at 3 h before the HWRF initialization, at the time of the HWRF initialization, and 3 h after the HWRF initialization, respectively. This procedure is termed FGAT, or First Guess at Appropriate Time.

HWRF employs the WRF model to downscale the GDAS forecasts to the 6- and 2-km grids

Table 4.1: Resolution (first row), number of grid points (top number in cell), and size (bottom number in cell) of the HWRF atmospheric grids.

for the vortex relocation and data assimilation procedures. This is done by using preprocessing utilities to interpolate the GDAS datasets to the HWRF 18-km domain, and then running two uncoupled 90-s WRF runs with three domains. These runs output "analysis" files, which are WRF restart files at t=0 (analysis time), and are referred to as the WRF Analysis run and the WRF Ghost run.

In HWRF operations at the National Weather Service, it is important that safeguards are put in place to prevent model failure. To account for the possibility that the GDAS dataset may be unavailable, WRF Ghost and WRF Analysis runs using the GFS dataset as initial conditions are also performed and can be used as a backup. In general, GDAS data is available, and the WRF Ghost and WRF Analysis runs initialized from the GFS are not ultimately used in the forecast process.

The WRF Analysis run has the main purpose of downscaling the global information to the HWRF high-resolution grids for use in the vortex relocation procedure discussed in further detail in Chapter 5. The WRF Ghost run downscales the global information to high-resolution grids that are slightly larger than their WRF forecast domain counterparts to provide first-guesses for the data assimilation procedure discussed further in Chapter 6. Depending on the domain, the WRF Ghost run is referred to as Ghost domain 2 (ghost_d02, the d02 counterpart) or Ghost domain 3 (ghost_d03, the d03 counterpart). Table 4.1 describes the grid spacing and size of the domains used in the HWRF main forecast run, the WRF Analysis, and the WRF Ghost runs. These domains are shown in Figure 4.1.

The HWRF includes two preprocessing packages to generate input files for WRF, the WRF Preprocessing System (WPS) and prep_hybrid. WPS consists of three programs to process input: geogrid interpolates static geographical data to the three HWRF domains; ungrib extracts meteorological fields from GRIB-formatted files and writes the fields to intermediate files; and metgrid horizontally interpolates the meteorological fields extracted by ungrib to the parent HWRF grid. The prep_hybrid utility horizontally interpolates the atmospheric fields represented as spectral coefficients in the global model files in binary format and native sigma vertical levels to the parent HWRF grid. The output of prep_hybrid and metgrid are utilized by the program real_nmm to vertically interpolate meteorological information to the HWRF vertical levels, resulting in a full set of 3D initial conditions that constitute
Figure 4.1: Example of the domains used by HWRF in the AL. The blue region is the outer 18-km domain. The purple solid boxes show the sizes of the vortex-following 6-km and 2-km domains, while the black dashed lines are the ghost domains for d02 and d03. The red box is the unified Atlantic MPIOM-TC domain.
4. HWRF Preprocessing System

the required WRF input. Both prep_hybrid and WPS are required because prep_hybrid only processes atmospheric data, so WPS is used to supply the initial conditions for soil temperature and moisture, as well as to supply the WRF model with the static information (topography, vegetation, etc.).

For general information about working with WPS, see the WRF-NMM documentation at:

http://www.dtcenter.org/HurrWRF/users/docs/index.php

As part of the vortex initialization procedure described in Chapter 5, the vortex from the processed global model analysis is removed and substituted with an improved vortex. To locate the vortex in the global model, the GFDL Vortex Tracker is run at the analysis time on the postprocessed 90-s output from the WRF Analysis run.

This chapter explains how to run the initialization procedure, including the launcher, WPS, prep_hybrid, real_nmm, WRF Analysis, and WRF Ghost to create the HWRF preliminary initial conditions.

4.2 Scripts

Three wrapper scripts are used to preprocess data for the atmospheric component of HWRF:

launcher_wrapper
init_gdas_wrapper
init_gfs_wrapper

The launcher wrapper calls scripts/exhwrf_launch.py to read the configuration files, set the output directory structures, and determine the location of the outer 18-km domain. The "init" wrapper scripts call the Python script scripts/exhwrf_init.py. For processing the GFS data, exhwrf_init.py is called once, and then three more times for processing GDAS data – once at each FGAT hour (3, 6, 9). Figures 4.2, 4.3, and 4.4 show the simplified outline of the processes that occur at each FGAT hour for both the GFS and GDAS initialization. The script exhwrf_init.py runs the three stages of WPS (geogrid, ungrib, and metgrid), prep_hybrid, real_nmm (to create initial and boundary conditions for the WRF Ghost and WRF Analysis runs), wrfghost, wrfanalysis, post, gribber, tracker, and realfcst (to create LBCs for the main forecast run). All these steps are needed for WRF initialization, and some of these are used again at later stages of the run (for example, post and tracker).
Figure 4.2: Simplified initialization procedures for the FGAT=3 valid 3 hours prior to HWRF initialization. All processes in the black box are run by calling `exhwrf_init.py` for GDAS at FGAT=3. Boxes with dashed outlines indicate modules and resulting files that are discussed in Chapter 5. Files that are outlined in heavy purple (dashed or solid) are used by subsequent processes described by Figure 6.1.
4. HWRF Preprocessing System

HWRF Initialization - Analysis Time

Figure 4.3: Simplified initialization procedures for the HWRF analysis time. All processes in the black box on the left are run by calling `exhwrf_init.py` for GDAS at FGAT=6, while the right black box are procedures from running `exhwrf_init.py` for GFS at analysis time. Boxes with dashed outlines indicate modules and resulting files that are discussed in Chapter 5. Files that are outlined in heavy purple (dashed or solid) are used by subsequent processes described by Figure 6.1.
4. HWRF Preprocessing System

HWRF Initialization - 3 h After Analysis

exhwrf_init.py for GDAS FGAT= 9

Figure 4.4: Simplified initialization procedures for the FGAT=9 valid 3 hours after HWRF initialization. All processes in the black box are run by calling exhwrf_init.py for GDAS at FGAT=9. Boxes with dashed outlines indicate modules and resulting files that are discussed in Chapter 5. Files that are outlined in heavy purple (dashed or solid) are used by subsequent processes described by Figure 6.1.

4.2.1 Overview of exhwrf_launch.py

1. Read in configure files from parm/ directory
2. Set the paths to the directories containing HWRF source code and to the Python scripts ($HOMEhwrf and $USHhwrf, respectively)
3. Set the storm ID
4. Initialize the directory structure for the HWRF workflow
5. Locate and extract TC Vitals for the current storm and cycle, then write information to $WORKhwrf
6. Using TC Vitals, determine the domain center and write output to file storminfo.hwrf_domain_center

68
4. HWRF Preprocessing System

7. Parse the configuration files and write configure and holdvars files to com/
8. Write a startfile to the launch directory (i.e., wrappers/)

Output files:

$\text{startfile}$ Name is defined in $\text{global_vars.ksh}$. Contains environment variables for the storm ID and paths to output data
$\text{storm1.conf}$ Located in com/ directory. Contains configuration information compiled from all configure files
$\text{storm1.holdvars.txt}$ Located in com/ directory. Only used in operational implementation of HWRF
$\text{SID.YYYYMMDDHH.domain.center}$ Coordinates of the domain center. $\text{SID}$ is the storm ID, i.e., 08L for Gonzalo (2014), and $\text{YYYYMMDDHH}$ is the analysis time

Status check:

The file $\text{startfile}$ defined in $\text{global_vars.ksh}$ has been written in the wrappers/ directory.

Usage:

To run $\text{exhwrf_launch.py}$, several arguments are required. Several arguments are provided within the wrapper, but it does not constitute an exhaustive list of options. Many additional arguments may be included with the submission of $\text{exhwrf_launch.py}$ by editing the $\text{launcher_wrapper}$. The $\text{launcher_wrapper}$ included with HWRF v3.7a submits $\text{exhwrf_launch.py}$ with the following arguments:

\[
\text{\$\{HOMEhwrf\}/scripts/exhwrf_launch.py } \text{YYYYMMDDHH} \text{ STID HISTORY} \backslash
\text{\$\{HOMEhwrf\}/parm config.EXPT=EXPT config.startfile=STARTFILE} \backslash
\text{config.HOMEhwrf=\$\{HOMEhwrf\} config.case_root=HISTORY} \backslash
\text{\$\{HOMEhwrf\}/parm/\text{hwrf_v3.7release.conf}}
\]

In the previous command, $\text{YYYYMMDDHH}$ should be replaced by the date to run, $\text{STID}$ represents the storm ID, i.e., 08L for Gonzalo (2014), and $\text{STARTFILE}$ is the launcher output file. The wrapper passes many of the values through environment variables, but values can be directly passed without the use of variables.

It is important to note that variables found in the configure files can also be passed in the command line, and do not need to be changed in the configure files. Yet another option is to use the configure files in the $\text{parm/}$ directory as a template by which to create your own configuration, and pass the new file as an argument to the launch script by appending the following argument:

\[
\text{\$\{HOMEhwrf\}/parm/my_hwrf_config.conf}
\]

Note that only those options meant to be changed need to be included in user-specific configuration files. The entire file should not be copied over.
4. HWRF Preprocessing System

4.2.2 Overview of the Init Scripts: exhwrf_init.py and Wrappers

In the following list, the top-level numbered items describe calls from the wrapper, either init_gdas_wrapper or init_gfs_wrapper, the alphabetic level represents calls from the script exhwrf_init.py, and the lowest level are calls to modules from within init.py.

1. Initialize the objects used to run all components of HWRF by calling hwrf_expt.init_module()

2. Call exhwrf_init.py to process the global input files using INIT_PARTS=ALL four times: once for GFS at analysis time from init_gfs_wrapper, then once for each FGAT hour for GDAS from init_gdas_wrapper
   a) Run initialization steps leading up to the WRF Analysis (run_through_anl()):
      i. geogrid
      ii. ungrib
      iii. metgrid
      iv. prep_hybrid
      v. realinit
      vi. runwrfanl
   b) Run additional initialization steps needed for data assimilation (run_init_after_anl()):
      i. ghost
      ii. post
      iii. gribber
      iv. tracker
   c) Run steps necessary to generate the LBCs for the main forecast (run_real_bdy()):
      i. ungrib
      ii. metgrid
      iii. prep_hybrid
      iv. realfcst

4.2.3 Overview of Initialization Modules

Geogrid  _____________________________

The run module for a Geogrid object resides in ush/hwrf/wps.py. The module performs the following tasks:

1. Link the GEOGRID.TBL and geog_data/ fixed files
2. Create the namelist
3. Run geogrid.exe

Output files:
4. HWRF Preprocessing System

geo_nmm.d01.nc  Static geographical data for the parent domain, with grid spacing of 0.135 degrees.
geo_nmm_nest.l01.nc  Static geographical data that covers the parent domain, with grid spacing of 0.045 degrees.
geo_nmm_nest.l02.nc  Static geographical data that covers the parent domain, with grid spacing of 0.015 degrees.

Status Check:

In the standard out file of either initialization task, you will find the line "INFO: WPS Geogrid completed.", once for gfsinit and once for each fgat hour of gdasinit.

Executables:

ggeogrid.exe

FUNCTION: Interpolates static geographical data to the parent and nest grids

INPUT: Fix files from 

GEOGRID.TBL - defines parameters of input data sets
namelist.wps - WPS namelist

OUTPUT: geo_nmm.d01.nc
geo_nmm_nest.l01.nc
geo_nmm_nest.l02.nc

USAGE: geogrid.exe

PrepHybrid

The run module for the PrepHybrid object is located in ush/hwrf/prep.py. The module performs the following tasks:

1. Copy the input files
2. Run hwrf_prep.exe
3. Link the output files

Output files for ICs:

hwrfinit_00  Global model spectral data preprocessed by hwrf_prep.exe and ready to be used by real_nmm to generate preliminary HWRF ICs.

Output files in for LBCs:
**4. HWRF Preprocessing System**

Global model spectral data preprocessed by hwrf_prep.exe and ready to be used by real_nmm to generate preliminary HWRF LBCs. The variable bc_index=0,1,...,n corresponds to the forecast files that need to be preprocessed to create the LBCs for the HWRF forecast.

**Status Check:**

In the standard output file of each initialization task, you will find the line "INFO: - exit status 0" for the task "prep_hybrid", once for gfsinit and once for each fgat hour in gdasinit.

**Executables:**

hwrf_prep.exe

**FUNCTION:** Preprocesses the GDAS or GFS spectral data on vertical sigma levels in binary format for use the by real_nmm

**INPUT:**
- geogrid.out - link to geo_nmm.d01.nc
- prep_hybrid.nl - prep_hybrid namelist
- fort.11 - link to gfsbc${bc_index}
- fort.44 - link to itime file contains $bc_index
- fort.45 - link to domain.center file
- gfsbc${bc_index} - link to the global spectral file [gdas1|gfs].${BKG_START_TIME}.sf${BKG_FCST_TIME} where $BKG_START_TIME is the GDAS or GFS initialization time and $BKG_FCST_TIME is time the GDAS or GFS forecast lead time. For example to create the 12-h LBCs for the HWRF forecast initialized at 2012102806, the GFS initialized at the HWRF analysis time is used, and these variables would be set to the following.

\[
\begin{align*}
BKG\_START\_TIME & = 2012102806 \\
BKG\_FCST\_TIME & = 012 \\
\end{align*}
\]

**OUTPUT:**
- hwrfinit_0
- hwrfbcs00_${bc_index}

**USAGE:**

\[$\text{PREP\_EXE } \$NX1 \$NY1 \$VERT\_LEV \$DXX \$DYY$\]

where $\$NX1, $\$NY1, and $\$VERT\_LEV are the output file grid dimensions in the meridional, zonal and vertical directions, and $\$DXX and $\$DYY are the horizontal grid spacing.

**Ungrib**

The run module for an Ungrib object resides in ush/hwrf/wps.py. The module performs the following tasks:
4. HWRF Preprocessing System

1. Create the namelist
2. Link the Vtable and input GRIB files
3. Run ungrib.exe

Output files:

The intermediate files written by ungrib.exe will have names of the form FILE:YYYY-MM-DD_HH (unless the prefix variable in hwrf.conf was set to a prefix other than "FILE").

Status Check:

In the standard out file of each initialization task, you will find the line "INFO: WPS Ungrib completed.", once for gfsinit and once for each fgat hour of gdasinit.

Executables:

ungrib.exe

FUNCTION: Extracts meteorological fields from GRIB formatted files and writes the fields to intermediate files

INPUT: GRIB files
Vtable – codes to interpret GRIB files
namelist.wps – WPS namelist

OUTPUT: FILE:YYYY-MM-DD_HH

USAGE: ungrib.exe

Metgrid ----------------------------------------

The run module for a Metgrid object resides in ush/hwrf/wps.py. The module performs the following tasks:

1. Create the namelist
2. Link the metgrid table
3. Copy in the output from geogrid and ungrib
4. Run metgrid.exe

Output files:

met_nmm.d01.YYYY-MM-DD_HH:MM:SS.nc

YYYY-MM-DD_HH:MM:SS refers to the valid date of the interpolated data in each file.

Status Check:
4. HWRF Preprocessing System

In the standard output file of each initialization task, you will find the line "INFO: WPS Metgrid completed.", once for gfsinit and once for each fgat hour of gdasinit.

**Executables:**

`metgrid.exe`

**FUNCTION:** Horizontally interpolates the meteorological fields extracted by ungrib to the model parent grid

**INPUT:**
- `METGRID.TBL` - parameters for interpolating each field
- `geo_nmm.d01.nc` - output of geogrid
- `namelist.wps` - WPS namelist

**FILE:** `YYYY-MM-DD_HH` - output of ungrib

**OUTPUT:** `met_nmm.d01.YYYY-MM-DD_HH:MM:SS.nc`

**USAGE:** `metgrid.exe`

**Realinit**

Realinit is a WRFTask object and its run module resides in `ush/hwrf/wps.py`. The module performs the following tasks:

1. Link the input and fixed files
2. Run `hwrf_swcorner_dynamic.exe` to calculate the istart and jstart values for a nest
3. Generate the namelist
4. Run `real_nmm.exe` to generate initial and boundary conditions. A high-resolution sea-mask data file (`fort.65`) for the entire outer domain is also generated. It is later used by the coupler.

**Output files:**

- `wrfinput_d01` ICs created from GDAS
- `wrfbdy_d01` LBCs created from GFS for the ghost and analysis runs
- `fort.65` High-resolution sea mask data

**Status Check:**

In the standard output file for gfsinit, you will find the line "INFO: gfsinit/realinit: completed". Similarly for gdasinit standard output, you will find the line "INFO: fgat.tYYYYMMDDHH/realinit: completed" where `YYYYMMDDHH` is the date string for each fgat hour valid time.
4. HWRF Preprocessing System

Executables:

real_nmm.exe

**FUNCTION:** Generates the initial and boundary conditions

**INPUT:** Fixed files†
- hwrfbcs_[0-21] - BC output of prep_hybrid
- hwrfinit_0 - IC output of prep_hybrid
- geo_nmm.d01.nc - d01 output from geogrid
- geo_nmm.101.nc - d02 output from geogrid
- geo_nmm.102.nc - d03 output from geogrid
- met_nmm.d01.YYYY-MM-DD_HH:00:00.nc - d01 output from metgrid

**OUTPUT:**
- fort.65
- wrfbdy_d01
- wrfinput_d01

**USAGE:** real_nmm.exe

hwrf_swcorner_dynamic.exe

**FUNCTION:** Calculates the lower-left corner of a nest as (i_parent_start, j_parent_start)

**INPUT:**
- storm.center - storm center location
- domain.center - domain center location
- fort.12 (namelist_main.input)

**OUTPUT:**
- set_nest, which contains the i_parent_start and j_parent_start. For example the following set_nest file specifies that the middle nest domain lower-left corner location is at (99,225) on the parent domain grid.
  - istart=00099
  - jstart=00225

**USAGE:** hwrf_swcorner_dynamic.exe

Realfcst

The process for realfcst is the same as realinit, except that realfcst runs for the length of the HWRF forecast, instead of only at the analysis time.
4. HWRF Preprocessing System

Runwrfanl

Runwrfanl is a WRFAnl4Trak object whose run module resides in `ush/hwrf/fcsttask.py`. The module performs the following tasks:

1. Link the input and fixed files
2. Run `hwrf_swcorner_dynamic.exe` to calculate the istart and jstart values for a nest
3. Generate the `namelist.input` for grids identical to the HWRF forecast grids
4. Run `wrf.exe` to make a 90-s run of WRF and generate two analysis output files

Output files:
- `trackin_d01` – storm location in the parent domain
- `wrfanl_d02_YYYY-MM-DD HH_00_00` – "analysis" file for 9-km nest
- `wrfanl_d03_YYYY-MM-DD HH_00_00` – "analysis" file for 3-km nest

Status Check:
In the standard output file, you will find the line "INFO: gfsinit/wrfanl: completed".

Executables:
- `wrf.exe`

FUNCTION: Atmospheric model component of HWRF

INPUT:
- Fixed files†
  - `geo_nmm.d01.nc` – d01 output from geogrid
  - `geo_nmm.101.nc` – d02 output from geogrid
  - `geo_nmm.102.nc` – d03 output from geogrid
  - `wrfinput_d01` – ICs for parent domain from realinit
  - `wrfbdy_d01` – LBCs for parent domain from realinit
  - `namelist.input` – WRF namelist

OUTPUT:
- `trackin_d01`
- `wrfanl_d02_YYYY-MM-DD HH_00_00`
- `wrfanl_d03_YYYY-MM-DD HH_00_00`

USAGE: `wrf.exe`

Runghost

Runghost is a WRFGhost object whose run module resides in `ush/hwrf/fcsttask.py`. The module performs the following tasks:

1. Link the input and fixed files
2. Run `hwrf_swcorner_dynamic.exe` to calculate the istart and jstart values for a nest
3. Generate the namelist.input for the ghost domains
4. Run `wrf.exe` to make a 90-s run of WRF and generate two analysis output files

Output files:

```
    wrfani_d02_YYYY-MM-DD_HH_00_00 - "ghost" analysis file for 9-km nest
    wrfani_d03_YYYY-MM-DD_HH_00_00 - "ghost" analysis file for 3-km nest
```

Status Check:

In the standard output file of gfsinit, you will find the line "INFO: gfsinit/ghost: completed". Similarly for gdasinit, you will find the line "INFO: fgat.yYYYYMMDDHH/ghost:", where `YYYYMMDDHH` is the date string of the FGAT hour valid time.

Executables

`wrf.exe`

FUNCTION: Atmospheric model component of HWRF

INPUT: Fixed files‡

- geo_nmm.d01.nc - d01 output from geogrid
- geo_nmm.101.nc - d02 output from geogrid
- geo_nmm.102.nc - d03 output from geogrid
- wrfini_d01 - ICs for parent domain from realinit
- wrfbdy_d01 - LBCs for parent domain from realinit
- namelist.input - WRF namelist

OUTPUT: `wrfani_d02_YYYY-MM-DD_HH_00_00`
- `wrfani_d03_YYYY-MM-DD_HH_00_00`

USAGE:

Post

Post is a PostOneWRF object whose run module resides in ush/hwrf/post.py. This instance of the module runs unipost.exe on the output of the 90-s WRF Analysis run. The purpose of this step is to destagger the HWRF native output, interpolate it vertically to pressure levels, compute derived variables, and output the result in GRIB format. Further details about the post objects, modules, and executables can be found in Chapter 10.

Output:

In the intercom/fgat.tYYYYMMDDHH/post/fgat.tYYYYMMDDHH/post directory, you will find the following file:

fgat.tYYYYMMDDHH_post-moad.egrb

Status check:

The line "INFO: state=COMPLETED" can be found in the standard output files for gdasinit and gfsinit for the "post" task. Performing a search for both of quoted strings should return one line for each FGAT hour for GDAS, and once for GFS.

Gribber

Gribber is a GRIBTask object and serves to regrib the output of post, interpolating the 18-km parent domain GRIB file to a 20°x 20°grid. This file is used as input to the GFDL Vortex Tracker. See Chapter 11 for more details about GRIBTask objects, modules, and executables.
4. HWRF Preprocessing System

Output:

In the intercom/fgat.tYYYYMMDDHH/regribber directory, you will find the files below, where stormname and sid are the name of the storm and the SID in lower case (e.g., gonzalo 08l for Hurricane Gonzalo):

- quarter_degree.grb
- {stormname}{sid}.YYYYMMDDHH.hwrftkr.grbf[-3,00,03]
- {stormname}{sid}.YYYYMMDDHH.hwrftkr.grbf[-3,00,03].grbindex
- subset.grb

Status check:

In the standard output files for gdasinit and gfsinit, you will find the following string on the same line as "regribber" for each FGAT hour: "WARNING: No subtasks incomplete. I think I am done running. Will exit regribber now."

Tracker ----------------------------------------

The GFDL Vortex Tracker is run on the GRIB file resulting from the gribber step above. The tracker object resides in ush/hwrf/tracker.py. More information about the tracker can be found in section 11.

Output:

In the intercom/fgat.tYYYYMMDDHHHH directory, you will find the file:

- gfs.track0.atcfunix - contains the storm center at initial time in the WRF analysis run output

Status Check:

In the standard output files for gdasinit and gfsinit, you should find the line "WARNING: Successful return status from gettrk.", once for gfsinit and once for each FGAT hour in gdasinit.
5.1 Introduction

The atmospheric component of HWRF, WRF-NMM, needs ICs and LBCs to produce forecasts. The GFS and GDAS fields are used to create the preliminary atmospheric fields, which are further improved through the vortex adjustment procedures and data assimilation to provide the final IC to WRF.

The vortex adjustment procedures are necessary because the initial vortex is often not realistically represented in the preliminary ICs since it originates from a low-resolution global data source, such as GDAS. Therefore, HWRF employs a sophisticated algorithm to adjust the vortex to match the observed storm intensity, location, and structure.

Initial conditions for HWRF d02 and d03 are created by ingesting GDAS fields onto the HWRF vortex initialization procedure. To prepare the fields for input in the vortex initialization, two 90-s atmosphere-only forecasts are conducted. These runs are referred to as the WRF Analysis and WRF Ghost runs, and their configuration is detailed in Chapter 4. Within the vortex relocation code, the fields are interpolated to the 3X domain, a temporary domain with 0.015° grid spacing. For historical reasons, some file names and executables use 4X when referring to the 3X domain.

The HWRF vortex relocation process has three possible stages, which are determined based on the intensity of the observed storm and on the availability of the 6-h forecast of the previous HWRF run. Figure 5.1 describes Stages 1 and 2, and Figure 5.2 describes Stage 3. If the previous cycle HWRF forecast exists, and if the observed storm intensity is at least 14 ms$^{-1}$, HWRF is run in cycled mode. In cycled mode, the the 6-h forecast vortex from the previous HWRF cycle, adjusted according to the TC Vitals, is used for initializing the
5. Vortex Relocation

current cycle. If those conditions are not met, the HWRF initialization is a "cold start".

For a cold start of storms with observed intensity less than 20 ms$^{-1}$, the GDAS vortex is adjusted and then used. Conversely, for storms with observed intensity greater than or equal to 20 ms$^{-1}$, a bogus vortex is used. A cycled run will go through all the three stages, while a "cold start" run will go through Stages 2 and 3 only.

**Stage 1:** The previous cycle 6-h HWRF forecast is separated into environment fields and a storm vortex. This step is run only for cycled cases.

**Stage 2:** The preliminary IC generated by real_nmm and the WRF ghost and analysis runs is separated into environment fields and a storm vortex.

**Stage 3:** The storm vortex from the 6-h forecast from the previous cycle (for cycled runs), from the GDAS, or from the bogus vortex is adjusted to match the observed location, intensity, and structure provided by the NHC for the current time. Then the vortex and environment fields are combined.
5. Vortex Relocation

**Stage I** is used to split the previous HWRF forecast into storm and environment so that the votes can be adjusted and relocated. This is not done when the storm is very weak, as it is best to use the GFS vortex in that case.

For obs intensity > 10, the information of location of HWRF vortex comes from the last cycle’s combined domain. However, for obs intensity <= 10, the last cycle’s parent domain track is used.

**Stage II** is used to split the global forecast to get the environment.

Figure 5.1: Simplified flow diagram of Stages 1 and 2 of the vortex relocation process.
5. Vortex Relocation

Figure 5.2: Simplified flow diagram of Stage 3 of the vortex relocation process.
5. Vortex Relocation

5.2 Scripts

The vortex improvement procedure is entirely driven by the wrapper script relocate_wrapper, which calls 4 instances of scripts/exhwrf_relocate.py. The first instance runs relocate on the 90-s WRF Analysis run initialized from the GFS analysis. The other three instances run relocate on the 90-s WRF Analysis runs created at each FGAT time for the domains initialized by the GDAS forecasts. If the relocation procedure using the GDAS-derived input files is successful, the relocate results from GFS-derived fields are discarded.

5.2.1 Overview of exhwrf_relocate.py

The numbered items in the following list indicate calls made from the exhwrf_relocate.py script, while the lower level list items are calls made within the Python modules.

1. Initialize the objects used to run all components of HWRF by calling hwrf_expt.init_module().
2. If GFS: run relocate at analysis time
   a) Stage 1
   b) Stage 2
   c) Stage 3
3. If GDAS: run relocate for each FGAT time
   a) Stage 1
   b) Stage 2
   c) Stage 3

5.2.2 Overview of the Relocate Modules

Stage 1

1. Copy the fixed files and input files to the working directory.
2. Check if the HWRF forecast from the previous cycle exists, and if the storm intensity is greater than 14 ms$^{-1}$; if not, continue to Stage 2.
3. Run diffwrf_3dvar.exe to convert the previous cycle forecast output wrfout_d0[1-3] into unformatted data files old_hwrf_d0[1-3] respectively.
4. Run merge_nest_4x_step12_3n.exe to merge old_hwrf_d0[1-3] onto 3X domain and produce a file containing the merged data: data_4x_hwrf.
5. Run hwrf_create_trak_guess.exe to produce a guess track (0,3,6,9 hour) for the current forecast using previous cycle forecast track.
6. Run wrf_split1.exe to separate data_4x_hwrf into two parts, an environment field (wrf_env) and a storm vortex (storm_pert). A storm radius data file
5. Vortex Relocation

(storm_radius) is also generated.

7. Run hwrf_pert_ctl1.exe to do adjustments to storm_pert. The new storm vortex data (storm_pert_new) as well as two files containing the storm size information (storm_size_p) and the symmetric part of the vortex (storm_sym) are generated.

Output files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>storm_size_p</td>
<td>Storm size information</td>
</tr>
<tr>
<td>storm_pert_new</td>
<td>New storm vortex after adjustments by hwrf_pert_ctl1.exe</td>
</tr>
<tr>
<td>storm_sym</td>
<td>Symmetric part of the vortex</td>
</tr>
<tr>
<td>storm_radius</td>
<td>Storm radius information</td>
</tr>
<tr>
<td>wrf_env</td>
<td>Environment field</td>
</tr>
</tbody>
</table>

Status Check:

If the line "INFO: Stage 1 completed" is found in the standard output, Stage 1 was successful.

Executables:

diffwrf_3dvar.exe

This executable serves two functions, denoted by 1 or 2 below.

FUNCTION: 1. Converts netCDF input to unformatted file (when first argument is "storm_relocate")
           2. Updates existing netCDF file with new unformatted file (when first argument is "3dvar_update")

INPUT: 1. netCDF format input files or previous cycle 6-h forecast
       2. Unformatted file containing new vortex fields

OUTPUT: 1. Unformatted data file
         2. Updated netCDF file

USAGE: 1. diffwrf_3dvar.exe storm_relocate input_file flnm3\output_file
       The command above writes the WRF file input_file into an unformatted file, output_file, which will be used in the vortex relocation procedures.
       2. diffwrf_3dvar.exe 3dvar_update input_file output_file
       The command above updates input_file with unformatted file output_file, which contains new vortex fields.

hwrf_merge_nest_4x_step12_3n.exe

FUNCTION: Merges inner and outer domains onto a 3X domain
5. Vortex Relocation

**INPUT:**
- \$gesfhr (=6) - last digit of the input/output fort file, i.e., fort.26
- \$st_int - the 68-69 characters in the tcvital.as
- \$ibgs(=1) - argument indicating if a cold start (ibgs=1) or a cycled run (ibgs=0)
- tcvitals.as (fort.11) - observed storm center
- old_hwrf_d01 or new_gfs_d01 (fort.26)
- old_hwrf_d02 or new_gfs_d02 (fort.36)
- old_hwrf_d03 or new_gfs_d03 (fort.46)

**OUTPUT:**
- data_4x_hwrf (fort.56) - merged data from inner and outer domains
- roughness1 or roughness2 (fort.66) - sea-mask (1=sea, 0=land) and ZNT (roughness length) merged onto the 3X domain.
- 30_degree_data (fort.61): partially merged data from inner and outer domains (not used later)

**USAGE:**
```
echo $gesfhr $st_int $ibgs $BASIN | hwrf_merge_nest_4x_10m2.exe
```

**hwrf_create_trak_guess.exe**

**FUNCTION:** Guesses storm center from previous 6-h forecast position

**INPUT:**
- $storm_id - storm ID
- $ih - model initial hour
- tcvitals.as (fort.11) - observed storm center
- hdas_atcfunix (fort.12) - track file from previous cycle 6-h forecast.

**OUTPUT:**
- trak.fnl.all (fort.30) - storm center guess (at 0, 3, 6, 9 h)

**USAGE:**
```
echo $storm_id $ih $BASIN | hwrf_create_trak_guess.exe
```

**hwrf_split1.exe**

**FUNCTION:** Splits the vortex from the background (environmental) field

**INPUT:**
- $gesfhr=6 - last digit of the input/output fort file, i.e., fort.26
- $ibgs =1
- $st_int - the 68-69 characters in the tcvital.as
- tcvitals.as (fort.11) - storm center obs
- data_4x_hwrf (fort.26) - merged data, on 3X domain, from inner and outer domains
- trak.fnl.all (fort.30) - storm center guess
- old_hwrf_d01 (fort.46) - outer domain data

86
5. Vortex Relocation

OUTPUT:  
- wrf_env (fort.56) - environmental flow  
- storm_pert (fort.71) - separated 3D vortex field  
- storm_radius (fort.85) - average of model and observed storm radius  
- rel_inform.$cdate (fort.52) - diagnostics file (obs-previous 6-h forecast)  
- vital_syn.$cdate (fort.55) - information for generating bogus if storm not found in previous 6-h forecast

USAGE:  
```
echo $gesfhr $ibgs $st_int $BASIN | hwrf_split.exe
```

hwrf_pert_ct1.exe

FUNCTION: Adjusts storm vortex (storm_pert)

INPUT:  
- $gesfhr (=6) - last digit of the input/output fort file, i.e., fort.26  
- hdas_atcfunix (fort.12) - storm track  
- tcvitals.as (fort.11) - storm center obs  
- wrf_env (fort.26) - environmental flow (from hwrf_split1.exe)  
- storm_pert (fort.71) - separated 3D vortex field (from hwrf_split1.exe)  
- roughness1 (fort.66) - sea-mask (1=sea, 0=land) and ZNT (roughness length) merged onto the 3X domain.

OUTPUT:  
- storm_pert_new (fort.58) - adjusted storm perturbation  
- storm_size_p (fort.14) - storm size information  
- storm_sym (fort.23) - storm symmetry information

USAGE:  
```
echo $gesfhr $BASIN | hwrf_pert_ct1.exe
```

Stage 2

1. Copy the fix files and namelist.  
2. Run `diffwrf_3dvar.exe` to convert `wrfinput_d0[1-3]` and `wrfghost_d0[2-3]` to binary files `new_gfs_d0[1-3]` and `new_ght_d0[2-3]`, respectively.  
3. Run `hwrf_create_trak_fnl.exe` to create `trak.fn1.all_gfs`, a guess track file from atcfunix.  
4. Run `hwrf_merge_nest_4x_step12_3n.exe` to merge all three HWRF domains (new_gfs_d0[1-3]) onto the 3X domain. This will generate the file containing the merged data on the 3X domain (data_4x_gfs) and a file containing sea-mask and roughness length data (roughness2).  
5. Run `hwrf_split1.exe` to separate the data_4x_gfs into environment data (gfs_env) and storm vortex (storm_pert_gfs). A file containing the storm radius information will be generated, too (storm_radius_gfs).

Status Check:
5. Vortex Relocation

In the standard output file, the line "INFO: Stage 2 completed" should exist.

Output files:

- gfs_env: environment fields from GFS data
- roughness2: sea-mask and roughness length from GFS data
- storm_pert_gfs: storm vortex from GFS data
- storm_radius_gfs: storm radius information from GFS data

Executables:

- diffwrf_3dvar.exe
  Refer to Stage 1 in section 5.2.2.

- hwrf_create_trak_fnl.exe
  Refer to Stage 1 in section 5.2.2.

- hwrf_merge_nest_4x_step12_3n.exe
  Refer to Stage 1 in section 5.2.2.

- hwrf_split1.exe
  Refer to Stage 1 in section 5.2.2.

Stage 3 ———————————————————

For a cold start or cycled start of a weak storm: The vortex and environment are obtained from the global data.

1. Link the input and fixed files.
2. Run hwrf_pert_ctl1.exe to adjust the GDAS (or GFS) vortex (storm_pert_gfs from Stage 2).
3. Run hwrf_anl_4x_step2.exe to adjust the storm vortex (storm_pert_gfs1) and add the new storm vortex to the environment flow (gfs_env) on the 3X domain grid. This will produce a new file (new_data_4x) containing the combined environment flow and the adjusted storm vortex.
4. When the combined vortex and environment flow is weaker than observations, discard the new file (new_data_4x), and run hwrf_anl_cs_10m.exe to further adjust the analysis. This produces a new version of new_data_4x containing the combined environment flow and adjusted vortex.
5. Run hwrf_inter_4to6.exe to interpolate the new_data_4x from the 3X domain onto the outermost HWRF grid. This will produce the new data_merge_d01. Input file for storm radius is storm_radius_gfs.
6. Run hwrf_inter_2to2.exe to interpolate the new_data_4x from the 3X domain onto the ghost_d02 grid. This will produce the new data_merge_g02.
7. Run hwrf_inter_2to2.exe to interpolate the new_data_4x from the 3X domain onto the ghost_d03 grid. This will produce the new data_merge_g03.
8. Run `diffwrf_3dvar.exe` to convert the merged data files (data_merge_d01 and data_merge_g0[2-3]) to NetCDF files (wrfinput_d01 and wrfghost_d0[2-3]).

For a cycled start of a strong storm: Performs all steps from cold/cycled weak storm except for Step 2. For a strong cycled storm, `hwrf_pert_ctl.exe` runs in Stage 1 and the vortex is taken from the previous HWRF forecast.

For a cold start of a strong storm: The vortex is an adjusted bogus vortex.

1. Link the input and fixed files.
2. Run `hwrf_anl_bogus_10m.exe` to create a bogus vortex and add it to the environment.
3. Perform Steps 5-8 of the weak storm procedure.

**Status Check:**

The line "INFO: Stage 3 completed" exists in the standard output.

**Executables:**

- `hwrf_pert_ctl.exe`
  
  Refer to Stage 1 in section 5.2.2.

- `hwrf_anl_4x_step2.exe`

  **FUNCTION:** Adjusts the storm vortex and adds the new storm vortex to the environment flow on the 3X domain grid

  **INPUT:**
  
  - `$gesfhr (=6)` - last digit of the input/output fort file, i.e., fort.26
  - `storm_size_p` (fort.14) - from `hwrf_pert_ctl.exe`
  - `tcvitals.as` (fort.11) - storm center obs
  - `hdas_atcfunix` (fort.12) - input track file from previous 6-h forecast
  - `storm_sym` (fort.23) - symmetric part of storm
  - `gfs_env` (fort.26) - GFS environmental flow
  - `roughness1` (fort.46) - roughness output from Stage 2 executable
  - `merge_nest_4x_step2.exe`
  - `storm_pert_new` (fort.71) - adjusted storm perturbation from `hwrf_pert_ctl.exe`

  **OUTPUT:**
  
  - `wrf_env_new` (fort.36) - new environmental flow
  - `new_data_4x` (fort.56) - adjusted vortex plue environment on 3X domain

  **USAGE:**
  
  `echo $gesfhr $BASIN 0 1 | hwrf_anl_4x_step2.exe`

- `hwrf_anl_cs_10m.exe`
5. Vortex Relocation

FUNCTION: Further adjusts the storm vortex when combined vortex plus environmental flow is less than the observed maximum wind speed

INPUT:  
$gesfhr (=6) – last digit of the input/output fort file, i.e., fort.26  
tcvitals.as (fort.11) – observed storm center  
wrf_env_new (fort.26) – new environmental flow (from hwrf_anl_4x_step2.exe)  
storm_sym (fort.23) – symmetric part of storm (from hwrf_pert_ctl1.exe)  
roughness (fort.46) – roughness info for boundary layer calculation (from hwrf_merge_nest_4x_step2.exe)  
storm_radius (fort.85) – from wrf_split.exe  
hwrf_storm_cyn_axisy_47 (fort.71, 72, 73, 74, 75, 78) input static vortex data  
hwrf_storm_20 (fort.76, 77) – input static vortex data

OUTPUT:  
new_data_4x (fort.56) – adjusted field on 3X domain when combined vortex + environmental flow is less than the observed maximum wind speed (replaces previous file)

USAGE:  
```
echo $gesfhr $BASIN | hwrf_anl_cs_10m.exe
```

hwrf_inter_4to6.exe

FUNCTION: Interpolates from 3X domain onto outer domain

INPUT:  
$gesfhr (=6) – last digit of the input/output fort file, i.e., fort.26  
tcvitals.as (fort.11) – observed storm center  
new_gfs_d01 (fort.26) – outer domain adjusted GFS data  
new_data_4x (fort.36) – adjusted storm  
new_gfs_d01 (fort.46) – outer domain adjusted GFS data  
storm_radius (fort.85)

OUTPUT:  
data_merge_d01 (fort.56) – merged data on outer domain

USAGE:  
```
echo $gesfhr $BASIN | hwrf_inter_4to6.exe
```

hwrf_inter_2to2.exe

FUNCTION: Interpolates from 3X domain to ghost_d02 or ghost_d03
5. Vortex Relocation

INPUT:  
$gesfhr (=6) - last digit of the input/output fort file, i.e., fort.26
tcvitals.as (fort.11) - observed storm center
new_data_4x (fort.26) - adjusted vortex + environment
new_ght_d0[2-3] (fort.36) - input ghost file in binary format from
either d02 or d03
new_gfs_d01 (fort.46) - outer domain adjusted GFS data

OUTPUT:  
data_merge_g0[2-3] (fort.56) - merged data on respective do-
main

USAGE:  
```bash
echo $gesfhr $BASIN | hwrf_inter_2to2.exe
```

diffwrf_3dvar.exe
Refer to Stage 1 in section 5.2.2.

hwrf_anl_bogus_10m.exe

FUNCTION: Creates a bogus storm and adds it to the environmental
flow

INPUT:  
$gesfhr (=6) - last digit of the input/output fort file, i.e., fort.26
tcvitals.as (fort.11) - observed storm center
gfs_env (fort.26) - GFS environmental flow
data_4x_gfs (fort.36) - merged GFS inner/outer domain data
roughness2 (fort.46) - roughness info for boundary layer calcula-
tion
storm_pert_gfs (fort.61) - separated GFS 3D vortex field
storm_radius_gfs (fort.85)
```
```
hwrf_storm_cyn_axisy_47 (fort.71,72,73,74,75,78) - input
static vortex data
hwrf_storm_20 (fort.76, 77) input static vortex data
```

OUTPUT:  
new_data_4x: combined environment flow and bogus field on the 3X
domain

USAGE:  
```bash
echo $gesfhr $BASIN | hwrf_anl_bogus_10m.exe
```
6.1 Introduction

The preliminary initial conditions created by downscaling the global model data and performing the vortex relocation procedures are further modified with data assimilation using GSI on the 6- and 2-km WRF Ghost domains. No data assimilation is done in the 18-km parent domain. The term HDAS, or HWRF Data Assimilation System, refers to the process of running GSI for data assimilation in HWRF.

The data assimilation in HWRF is performed using the hybrid ensemble-variational method. This indicates that the background error covariance information is a combination of two sources, a static, pregenerated matrix from the global model, and a flow-dependent matrix derived from an ensemble of 6-h forecasts. Because HWRF uses an ensemble, but does not feedback into it, this procedure is termed "one-way hybrid". The 2015 HWRF operational implementation uses a 40 member HWRF ensemble for the North Atlantic and Eastern Pacific domains when inner-core data from NOAA’s P3 TDR are available. However, this procedure is not supported in the HWRF v3.7a public release. Users can still use the GFS ensemble for hybrid ensemble-variational data assimilation. For more information on the ensemble-variational method, refer to the HWRF v3.7a Scientific Documentation available from the DTC website (www.dtcenter.org/HurrWRF/users).

The datasets assimilated in operations in the 6-km (d02) and 2-km (d03) domains are described in the HWRF Scientific Documentation. HWRF has the capability of assimilating tropical cyclone inner-core data such as the NOAA’s P3 TDR observation. To collect inner-core observations, an aircraft has to penetrate the target TC multiple times to finish one mission, which may take several hours; therefore the observations in one TDR data set are collected at different times. In order for GSI to calculate the innovation, defined as the
6. Data Assimilation

The difference between the first guess and the analysis, it needs to have the first guess and the observations valid at the same time. To accomplish this for observations that span a range of times, the First Guess at Appropriate Time (FGAT) procedure is used. In FGAT, first-guess fields valid at various times are supplied to GSI, which then interpolates the data to the time in which each observation was taken. For HWRF, first-guess fields are created at three time levels: 3 h before the HWRF initial time (Figure 4.2); at the HWRF initial time (Figure 4.3); and 3 h after the HWRF initial time (Figure 4.4). To create the three first-guesses, the real_nmm, short WRF forecasts, and vortex adjustment procedures are performed three times. This produces all of the ghost d03 and ghost d02 output files that are used by GSI in its FGAT operation (Figure 6.1).

After the data is assimilated in the ghost d02 and ghost d03 domains, the preliminary analysis for the parent domain, the middle and inner domain output from the WRF Analysis, and the ghost d02 and ghost d03 GSI analysis (which used FGAT) are merged to produce the final atmospheric IC for the 5-day forecast. To perform the data assimilation in the ghost domain, users should run GSI and then merge. For more details about GSI, please consult the GSI Users’ Guide available from the DTC at http://www.dtcenter.org/com-GSI/users/docs/users_guide/GSIUserGuide_v3.4.pdf.

Figure 6.1: Simplified GSI and merge procedures. Purple outlined boxes correspond to the purple outlined boxes of the Figures in section 4.2. Blue boxes are NetCDF files.

6.2 Scripts

The HWRF data assimilation component begins by running a data preparation script, bufr-prep_wrapper, which calls scripts/exhwrf_bufrprep.py. Next two wrapper scripts, gsi_d02_wrapper and gsi_d03_wrapper are run. These wrappers are responsible for calling their respective instances of scripts/exhwrf_gsi.py.
6. Data Assimilation

6.2.1 Overview of `exhwrf_bufrprep.py`

1. Initialize the objects used to run all components of HWRF by calling `hwrf_expt.init_module()`.
2. If GSI is enabled, run the bufr data preparation script.

6.2.2 Overview of the Bufrprep Module

The run module for the bufr data preparation step (an FGATGSI class object) is located in `ush/hwrf/bufrprep.py`, and is responsible for the following tasks:

1. Copy the prepbufr files
2. Link the specified observations files
3. Run a prepbufr processing algorithm based on the choice of `bufr-prep.prepbufrprep` flag in `hwrf.conf`.
   - Case 0: Make no change. Do not run a program.
   - Case 1: Remove some inner-core data by running `hwrf_rem_prepbufr_typ_in_circle`.
   - Case 2: Change the flag for mass and dropsonde u, v data by running `hwrf_change_prepbufr_qm_in_circle`.
   - Case 3: Unflag HS3 dropsonde data by running `hwrf_change_prepbufr_qm_typ`. (Default value)

Output files:

```
gsi_status.{STORMNAME}{SID}.YYYYMMDDHH  GSI status file
```
```
gfs.tHHz.prepbufr.nr  prepbufr data
```

Status Check:

In the standard output file, you will find: INFO: – exit status 0.

Executables:

```
hwrf_rem_prepbufr_typ_in_circle.exe
```

FUNCTION: Removes some inner core data

INPUT: `prepbufr.ALL (fort.21)` – prepbufr file containing original observations

\$RLATC – environment parameter for storm latitude
\$RLONC – environment parameter for storm longitude
\$RRADC – environment parameter for the radius of a circle centered at TC center

OUTPUT: `prepbufr (fort.51)` – edited prepbufr file
6. Data Assimilation

**hwrf_rem_prepbufr_typ_in_circle.exe**

**FUNCTION:** Flags or unflags observations of mass and dropsonde u, v data

**INPUT:**
- `prepbufr.ALL (fort.21)` - prepbufr file containing original observations
- `$RRADC` - environment parameter for half the side length of a square centered at TC center
- `$RRADC` - environment parameter for the radius of a circle centered at TC center

**OUTPUT:**
- `prepbufr (fort.51)` - edited prepbufr file

**USAGE:** `hwrf_rem_prepbufr_qm_in_circle.exe`

**hwrf_change_prepbufr_qm_typ.exe**

**FUNCTION:** Unflags HS3 dropsonde data

**INPUT:**
- `prepbufr.ALL (fort.21)` - prepbufr file containing original observations

**OUTPUT:**
- `prepbufr (fort.51)` - edited prepbufr file

**USAGE:** `hwrf_change_prepbufr_qm_typ.exe`

### 6.2.3 Overview of `exhwrf_gsi.py`

1. Initialize the objects used to run all components of HWRF by calling `hwrf_expt.init_module()`.
2. Run GSI for the appropriate domain.

### 6.2.4 Overview of the GSI Module

The run module for GSI (an FGATGSI class object) is located in `ush/hwrf/gsi.py`, and is responsible for the following tasks:

1. Link the fixed files
2. Link the GFS ensemble files
3. Link the observation files
4. Link the bias correction files
6. Data Assimilation

5. Create a namelist for the GSI analysis
6. Copy the background file (wrf_inout) from the corresponding WRF Ghost run
7. Run gsi.exe

Output files:

stdout: The standard text output file. It is the file most often used to check the GSI analysis processes as it contains basic and important information about the analyses.

wrf_inout: Analysis results; format is same as the input background file

Status Check:

In the standard output file, you will find the line "INFO: GSI succeeded" followed by the domain for which the assimilation was run (stormlghost_parent is the intermediate nest and stormlghost is the innermost nest).

Executables:

gsi.exe

FUNCTION: Performs the GSI 3D-V AR data assimilation analysis

INPUT:  
gsiparm.anl – GSI namelist, created by the script by modifying template /parm/hwrf_gsi.nml
filelist – ASCII file with 80 lines, each one containing a file name for a GFS ensemble member (used for ensemble-based background covariance)
satbias_angle – file containing information on satellite angle, from dataset directory
satbias_in – file containing information on satellite bias, from dataset directory
wrf_inout – background file, copied from WRF Ghost output
Various observations in BUFR and prepBUFR format

OUTPUT: wrf_inout – analysis results if GSI completes successfully. The format is the same as the background file.

satbias_out – Newly computed satellite bias

USAGE: gsi.exe < gsiparm.anl
7.1 Introduction

Once the HWRF atmospheric initialization has been completed with the use of the vortex relocation and data assimilation, the adjusted ICs on all grids must be merged to provide the final ICs for the HWRF 5-day forecast. The origin of the files going into the merge procedure is shown in Figure 6.1. The merge is run by the wrapper script `merge_wrapper`. A description of the domains used in HWRF is included in section 4.1.

7.2 Scripts

Merge is run by submitting the `merge_wrapper`, which sets necessary environment variables before running Python script `exhwrff_merge.py`.

7.2.1 Overview of `exhwrff_merge.py`

1. Initialize the objects used to run all components of HWRF by calling `hwrff_expt.init_module()`.
2. Run the `gdas_merge` Python module.
7. Merge

7.2.2 Overview of Merge Module

Merge is a RelocationTask object whose run module lives in ush/hwrf/relocate.py and is responsible for the following tasks:

1. Copy the input files.
2. Check to see whether storm_radius file exists from relocate process and contains information.
3. Run diffwrf_3dvar.exe to convert the netCDF format wrfinput_d0[1-3] and wrfghost_d0[2-3] to unformatted data files new_hdas_d01, new_gfs_d0[2-3], and new_ght_d0[2-3].
4. Run hwrf_inter_2to1.exe to interpolate the data in file new_ght_d03 and new_gfs_d03 to the inner-nest domain grid. This will produce the merged data on the inner-nest grid (data_merge_d03).
5. Run hwrf_inter_2to1.exe to interpolate the data in file new_ght_d02 and new_gfs_d02 to the inner-nest domain grid. This will produce the merged data on the inner-nest grid (data_merge_d02).
6. Run hwrf_inter_2to6.exe to interpolate the files new_hdas_d01, new_gfs_d02, and new_ght_d02 to the outer domain grid. This will produce the merged data on the outer domain grid (data_merge_d01).
7. Run diffwrf_3dvar.exe to convert the unformatted files data_merge_d0[1-3] to the netCDF format files wrfinput_d0[1-3].
8. Deliver the products.

Output files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wrfinput_d01</td>
<td>IC for the outer domain containing the new vortex</td>
</tr>
<tr>
<td>wrfinput_d02</td>
<td>IC for the middle-nest domain containing the new vortex</td>
</tr>
<tr>
<td>wrfinput_d03</td>
<td>IC for the inner-nest domain containing the new vortex</td>
</tr>
</tbody>
</table>

Status Check:

Check that output files exist in the com/ directory for the current cycle. The line "INFO: exhwrf_merge has completed" will also appear near the end of the standard output file.

Executables:

- diffwrf_3dvar.exe
  Refer to Stage 1 in section 5.2.2.
hwrf_inter_2to1.exe

**FUNCTION:** Interpolates from ghost domains to nest domains (*DOMAIN* is "02" or "03")

**INPUT:**
- $gesfhr$ (=6) - last digit of the input/output fort file, i.e. fort.26
- new_ght_d(*DOMAIN*) (fort.26) - data on ghost domain
- new_gfs_d(*DOMAIN*) (fort.36) - data on nest domain

**OUTPUT:**
- data_merge_d(*DOMAIN*) (fort.56) - interpolated data on inner domain

**USAGE:**
```
echo $gesfhr $BASIN | hwrf_inter_2to1.exe
```

hwrf_inter_2to6.exe

**FUNCTION:** Interpolates data from ghost domain to outer domain.

**INPUT:**
- $gesfhr$ (=6) - last digit of the input/output fort file, i.e. fort.26
- new_gfs_d02 (fort.26) - data on HWRF middle nest grid
- new_ght_d02 (fort.36) - data on ghost d03 grid
- new_hdas_d01 (fort.46) - data on outer domain grid
- storm_radius (fort.85) - storm radius obtained from wrf_split1.exe in either Stage 1 (cycled run) or Stage 2 (cold start)

**OUTPUT:**
- data_merge_d01 (fort.56) - interpolated data on outer domain

**USAGE:**
```
echo $gesfhr $BASIN | hwrf_inter_2to6.exe
```
8.1 Introduction

This chapter explains how to run the initialization of the MPIPOM-TC component of the HWRF model, available from the DTC. Users are also encouraged to read the HWRF v3.7a Scientific Documentation.

8.2 Scripts

The initialization of the HWRF ocean model, MPIPOM-TC, is accomplished by running the init_ocean_wrapper, which is responsible for linking the ocean executables to the exec/directory and running exhwrf_ocean_init.py to generate updated initial conditions for the ocean forecast component of HWRF.

8.2.1 Overview of exhwrf_ocean_init.py

1. Initialize the objects used to run all components of HWRF by calling hwrf_expt.init_module().
2. Run `pominit`. If successful, write a status file to indicate that the forecast will be coupled, otherwise indicate that the forecast will be uncoupled.

### 8.2.2 Overview of Ocean Init Modules

1. Determine the region for which the ocean model will be run. Currently supported options are Transatlantic, East Pacific, West Pacific, North Indian, South Indian, Southwest Pacific, and Southeast Pacific domains, as described in the HWRF Scientific Documentation.

2. Determine the ocean initial condition module to be used. Currently supported options, which are consistent with the 2015 operational configuration of HWRF, include the Generalized Digital Environmental Model (GDEM) temperature and salinity climatology with feature-based modifications for the transatlantic domain and the unmodified GDEMv3 climatology for the East Pacific domain. If coupling with the ocean is configured for other basins, a non-operational procedure, GDEMv3 is also used.

3. Link the input and fix files.

4. Run `gfdl_getsst.exe` to obtain the sea surface temperature and land/sea mask from the GFS analysis.

5. Run `gfdl_sharp_mcs_rf_l2m_rmy5.exe` (in transatlantic domain only) to assimilate ocean features, including major fronts and eddies, and sharpen the frontal gradients.

6. Run `transatl106prep.xc` (in transatlantic domain only) to blend the sharpened GDEM and the unsharpened GDEM along 50 W longitude.

7. Prepare ocean initial conditions for MPIPOM-TC Phase 1. By default, `pomprep_fbtr.xc` is used for the transatlantic domain, and `pomprep_gdm3.xc` is used for the East Pacific domain. Also, by default, both executables are set to assimilate the GFS SST analysis into the upper ocean mixed layer, creating an ocean initial condition at the sea surface that is identical to the atmospheric initial condition at the sea surface.

8. Run `hwrf_ocean_init.exe` for Phase 1 to spin up the ocean currents. The SST is held constant during Phase 1. Historically, Phase 1 has also been known as Phase 3, so the terms Phase 1 and Phase 3 are sometimes used interchangeably.

9. Run `hwrf_ocean_init.exe` for Phase 2 to generate the cold wake at the sea surface prior to the start of the coupled model forecast. Historically, Phase 2 has also been known as Phase 4, so the terms Phase 2 and Phase 4 are sometimes used interchangeably.

### Executables:

`gfdl_getsst.exe`

**FUNCTION:** Extract SST, land/sea mask, and lon/lat data from the GFS spectral files.

**INPUT:**
- `for11` (gfs.YYYYMMDDHH.tHHz.sfcanl)
- `fort.11` (gfs.YYYYMMDDHH.tHHz.sfcanl)
- `fort.12` (gfs.YYYYMMDDHH.tHHz.sfcanl)
8. Ocean Initialization for MPIPOM-TC

**OUTPUT:**
- `fort.23 (lonlat.gfs)`
- `fort.74 (sst.gfs.dat)`
- `fort.77 (mask.gfs.dat)`
- `getsst.out`

**USAGE:**
```
gfdl_getsst.exe > getsst.out
```

gfdl_sharp_mcs_rf_l2m_rmy5.exe

**FUNCTION:** Run the feature-based sharpening program, which takes the GDEM T/S climatology, horizontally interpolates it onto the old POM-TC grid for the United domain, and employs the diagnostic, feature-based modeling procedure, as described in the HWRF Scientific Documentation. This executable is called for the transatlantic domain only.

**INPUT:**
- `input_sharp`
- `fort.66 (gfdl_ocean_topo_and_mask REGION)`
- `fort.8 (gfdl_gdem.MM.ascii)`
- `fort.90 (gfdl_gdem.MM±1.ascii)`
- `fort.24 (gfdl_ocean_readu.dat.MM)`
- `fort.82 (gfdl_ocean_spinup_gdem3.dat.MM)`
- `fort.50 (gfdl_ocean_spinup_gspath.MM)`
- `fort.55 (gfdl_ocean_spinup.BAYuf)`
- `fort.65 (gfdl_ocean_spinup.FSgsuf)`
- `fort.75 (gfdl_ocean_spinup.SGYREuf)`
- `fort.91 (mmdd.dat)`
- `fort.31 (hwrf_gfdl_loop_current_rmy5.dat.YYYYMMDD)`
- `fort.32 (hwrf_gfdl_loop_current_wc_ring_rmy5.dat.YYYYMMDD)`

**OUTPUT:**
- `fort.13 (gfdl_initdata.united.MM)`
- `sharp_mcs_r_l2b.out`

**USAGE:**
```
gfdl_sharp_mcs_rf_l2m_rmy5.exe < input_sharp > sharp_mcs_r_l2b.out
```

transatl06prep.xc

**FUNCTION:** Blend T/S between sharpened GDEM and unsharpened GDEM along 50W. This executable is called for the transatlantic domain only.

**INPUT:**
- `fort.8 (gfdl_gdem.MM.ascii)`
- `fort.90 (gfdl_gdem.MM±1.ascii)`
- `fort.91 (mmdd.dat)`
- `fort.13 (gfdl_initdata.united.MM)`
8. Ocean Initialization for MPIPOM-TC

OUTPUT:  
fort.113 (gfdl_initdata.REGION.MM)
transatl06prep.out

USAGE:  transat106prep.xc > transat106prep.out

pomprep_fbtr.xc

FUNCTION: Read sharpened and blended GDEM climatology, horizontally interpolate it onto the high-resolution MPIPOM-TC grid, incorporate the bathymetry and a land-sea mask, assimilate the GFS SST, and prepare the ICs for MPIPOM-TC. This executable is called for the transatlantic domain only.

INPUT:  
input
fort.13 (gfdl_initdata.transatl.MM)
fort.66 (gfdl_ocean_topo_and_mask.REGION.lores)
fort.21 (sst.gfs.dat)
fort.22 (mask.gfs.dat)
fort.23 (lonlat.gfs)

OUTPUT:

  - `STORM.grid.nc`
  - `STORM.ts_clim.nc`
  - `STORM.ts_initial.nc`
  - `STORM.uv_initial.nc`
  - `restart.phase1.nc`

**OUTPUT:**
- **For Phase 1**
  - `restart.phase1.nc`
  - `STORM.0000.nc`
  - `STORM.0001.nc`
  - `STORM.0002.nc`
- **For Phase 2**
  - `restart.phase2.nc`
  - `STORM.0000.nc`
  - `STORM.0001.nc`
  - `STORM.0002.nc`
  - `STORM.0003.nc`

**USAGE:**
```
hwrf_ocean_init.exe > ocean_init.out
```
8. Ocean Initialization for MPIPOM-TC

8.3 MPIPOM-TC Diagnostics

MATLAB-based diagnostic tools are now available to plot the SST, subsurface temperature, and ocean current vectors at various times throughout the forecast and at various zoom levels. A README file in pomtc/ocean_diag/matlab explains how to use the mature tools. Additional community-based plotting tools are also provided for the creation of plots such as vertical cross sections.

8.4 User-provided Datasets for MPIPOM-TC Initialization

To initialize MPIPOM-TC with user-provided datasets, it is necessary to turn off SST assimilation by choosing $\text{SSTASIM} = \text{False}$ in master.py.

The user-provided datasets should be in the same format as the Navy Coupled Ocean Data Assimilation (NCODA) datasets. Once the data is in this format, MPIPOM can be run with this data by selecting the NCODA option in master.py script.

Example: $\text{oinit\_d} = \{”transatl”:”NCODA”\}$

A FORTRAN program to generate data in this format is provided below:

```fortran
INTEGER, PARAMETER :: nx=2161, ny=1051, nl=34
INTEGER, PARAMETER :: reclen=nx*ny*4
REAL, DIMENSION(nl) :: zncda
REAL, DIMENSION(nx,ny) :: alonin, alatin
REAL, DIMENSION(nx,ny,nl) :: temp, salt

! Vertical depth levels where data need to be
zncda = (0., 2.5, 7.5, 12.5, 17.5, 22.5, 32.5,
        40., 50., 62.5, 75., 100., 125., 150.,
        200., 300., 400., 500., 600., 700., 800.,
        900., 1000., 1100., 1200., 1300., 1400., 1500.,
        1750., 2000., 2500., 3000., 4000., 5000.)

fname = ’grdlon_sfc_000000_000000_1o2161x1051_datafld’

CLOSE(48)
CLOSE(49)
# Forecast Model

## 9.1 Introduction

The operational HWRF, which runs in all basins, is an atmosphere-ocean-coupled forecast system, which includes an atmospheric component (WRF-NMM), an ocean component (MPIPOM-TC), and the NCEP Coupler. Therefore, HWRF is a Multiple-Program Multiple-Data (MPMD) system which consists of three executables, WRF, MPIPOM-TC, and Coupler. After the ocean and atmosphere initializations are successfully completed, the coupled HWRF forecast can be submitted. In the Central, West and South Pacific, and Indian Ocean basins, HWRF is run operationally in atmosphere standalone mode, that is, uncoupled.

## 9.2 Scripts

The wrapper script `forecast_wrapper` is responsible for calling the Python script `ex-hwrf_forecast.py` in the `scripts/` directory. The wrapper script sets the number of tasks for the parallel forecast job. In operations, 477 tasks are used: 464 for the WRF forecast, nine for the MPIPOM-TC, and four for the NCEP Coupler. While this configuration is recommended, you may change the total number of tasks to reflect the following relationship,

\[
TOTAL\_TASKS = np + 9 + 4, \tag{9.1}
\]

where \(np\) is an integer multiple of 4. The total number of processors used should match TOTAL\_TASKS.
9. Forecast Model

For uncoupled runs, you should change the variable `TOTAL_TASKS` in `forecast_wrapper` to reflect the reduction of tasks (i.e., subtract 13 for the MPIPOM-TC and Coupler). The number of processors chosen should also be consistent with the product of the WRF namelist variables `runwrf.nproc_x` and `runwrf.nproc_y` that are originally set in `system.conf` and can be changed by passing arguments to `exhwrf_launch.py` inside the `launcher_wrapper`.

9.2.1 Overview of `exhwrf_forecast.py`

1. Initialize all of the objects used to run HWRF
2. Run the HWRF main forecast, coupled or uncoupled (`runwrf.run`)

9.2.2 Overview of the Forecast Module

For coupled forecasts, `runwrf` is an object of the `WRFCoupledPOM` subclass of `fcst-task.WRFAtmos`. The run module is responsible for the following tasks:

1. Link the input files required by WRF (fix files, initial and boundary condition files, and geographical data files).
2. Make the Coupler namelist.
3. Make the POM namelist.
4. Copy POM inputs.
5. Run `hwrfswcorner_dynamic.exe` to calculate the location of the middle nest.
6. Make the WRF namelist.
7. Submit the MPI forecast run (three executables: `wrf.exe`, `hwrfocean_fcst.exe`, `hwrf_wm3c.exe`).

Output files:

Primary output files, containing a large number of forecast variables, are produced every hour for the first nine hours, then every three hours.

```
wrfout_d01_yyyy-mm-dd_hh_mm_ss
wrfout_d02_yyyy-mm-dd_hh_mm_ss
wrfout_d03_yyyy-mm-dd_hh_mm_ss
```

Auxiliary output files containing accumulated precipitation and 10-m winds, with hourly output in a single file for each domain.

```
wrfdiag_d01
wrfdiag_d02
wrfdiag_d03
```
9. Forecast Model

Text file with time series of storm properties.

hifreq_d03.htcf

File hifreq_d03.htcf has nine columns containing the following items:

1. Forecast lead time (s)
2. Minimum Sea Level Pressure (MSLP) in the inner nest (hPa)
3. Latitude of grid point with minimum sea level pressure
4. Longitude of grid point with minimum sea level pressure
5. Maximum wind in the inner nest at the lowest model level (kt)
6. Latitude of grid point with the maximum wind
7. Longitude of grid point with the maximum wind
8. Latitude of the location of the center of the inner nest
9. Longitude of the location of the center of the inner nest

The ocean model will produce diagnostic output files with the following naming convention:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STORMNAME.00DD.nc</td>
<td>Ocean forecast output for each day (DD) in NetCDF format</td>
</tr>
<tr>
<td>flux.00DD</td>
<td>Forecast ocean flux for each day</td>
</tr>
<tr>
<td>sst.00DD</td>
<td>Forecast sea surface temperature for each day</td>
</tr>
<tr>
<td>sstuvhflux.00HH</td>
<td>Additional fields used for diagnostics, per hour</td>
</tr>
</tbody>
</table>

Status Check:

To check whether the run was successful, look for "SUCCESS COMPLETE WRF" at the end of the log file (e.g., rsl.out.0000). This check is also done in the code, and can be found in the standard output file.

Executables:

hwrf_swcorner_dynamic.exe
   Refer to section 4.2.3.

wrf.exe
   FUNCTION: Atmospheric component of HWRF
   INPUT:  
   geo_nmm.d01.nc - Geogrid static files for d01  
   geo_nmm_nest.101.nc - Geogrid static files for d02  
   geo_nmm_nest.102.nc - Geogrid static files for d03  
   wrfbdy_d01 - LBCs for d01  
   wrfinput_d01 - ICs for d01  
   wrfanl_d02_YYYY-MM-DD_HH_00_00 - ICs for d02  
   wrfanl_d03_YYYY-MM-DD_HH_00_00 - ICs for d03  
   namelist.input - Example in Appendix B  
   fort.65  
   WRF Fix files (Refer to section 4.2.3)
9. Forecast Model

**OUTPUT:**
- `wrfout_d01_YYYY-MM-DD_HH_00_00`
- `wrfout_d02_YYYY-MM-DD_HH_00_00`
- `wrfout_d03_YYYY-MM-DD_HH_00_00`
- `wrfdiag_d01`
- `wrfdiag_d02`
- `wrfdiag_d03`
- `hifreq_d03.htcf`

**USAGE:** For a coupled HWRF forecast, `wrf.exe` must be submitted with the coupler and the ocean model. Refer to MPI Explanation below. For an uncoupled run, you only need to issue the executable.

**FUNCTION:**
- `hwrf_ocean_fcst.exe`

**INPUT:**
- `STORM.el_initial.nc`
- `STORM.grid.nc`
- `STORM.ts_clim.nc`
- `STORM.ts_initial.nc`
- `STORM.uv_initial.nc`
- `restart.phase2.nc`

**OUTPUT:**
- `STORM.0000.nc`
- `STORM.0001.nc`
- `STORM.0002.nc`
- `STORM.0003.nc`
- `STORM.0004.nc`
- `STORM.0005.nc`

**USAGE:** For a coupled HWRF forecast, the ocean model `hwrf_ocean_fcst.exe` must be submitted to the computers with the atmosphere model `wrf.exe` and the coupler `hwrf_wm3c.exe`. Refer to the MPI explanation below.

**FUNCTION:** Coupler that links the atmospheric component and oceanic component

**INPUT:**
- `cpl.nml` - coupler namelist

**OUTPUT:** None

**USAGE:** Refer to the MPI explanation below
9. Forecast Model

Explanation of the MPI command for the forecast model

As mentioned in section 9.1, HWRF can be run as either a coupled or uncoupled model of the atmosphere and ocean. The operational HWRF runs are coupled in the AL and EP basins. By default, the scripting system submits coupled runs in the AL and EP basins when `config.run_ocean=yes in hwrf_basic.conf`, and uncoupled runs in other basins (`config.run_ocean=no`). If an uncoupled run in the AL or EP basins is desired, refer to section 3.8.1 for configuration details.

- **Coupled**

  With LSF, using the command `mpirun.lsf`

  ```
  mpirun.lsf -cmdfile cmdfile
  ```

  where `cmdfile` is a file containing the list of executables. For example, the `cmdfile` file below indicates that the coupled run will be submitted to 477 processors, four for the coupler (`hwrf_wm3c.exe`), nine for the ocean domain (`hwrf_ocean_fcst.exe`) and 464 for `wrf.exe`.

  ```
  hwrf_wm3c.exe
  hwrf_ocean_fcst.exe
  wrf.exe
  wrf.exe
  wrf.exe
  ```

  With MOAB/Torque, using the command `mpiexec`

  ```
  mpiexec -np 4 ./hwrf_wm3c.exe ; -np 9 ./hwrf_ocean_fcst.exe ; -np 464 ./wrf.exe
  ```

  For example, the previous command will run the coupled model using 477 processors, four for the coupler (`hwrf_wm3c.exe`), nine for the ocean domain (`hwrf_ocean_fcst.exe`), and 464 for `wrf.exe`.

- **Uncoupled**

  - With LSF, using the command `mpirun.lsf`

    ```
    mpirun.lsf -procs 464 ${WRF_ROOT}/main/wrf.exe
    ```

  - With MOAB/Torque, using the command `mpiexec`

    ```
    mpiexec -np 464 ${WRF_ROOT}/main/wrf.exe
    ```

Note that the number of processors should be changed when running a reduced-resolution 27/9/3-km HWRF configuration. The coupled system in the 27/9/3-km configuration runs by default with a total of 210 processors: 200 for the atmosphere, one for the coupler, and nine for the ocean.
HWRF Post-Processor

10.1 Introduction

The NCEP UPP is used to destagger the HWRF parent- and nest-domain output, compute diagnostic variables, and interpolate the output from the native WRF grids to NWS standard levels (pressure, height etc.) and standard output grids (latitude/longitude, Lambert Conformal, polar-stereographic, Advanced Weather Interactive Processing System grids, etc.). The UPP outputs files in GRIB format. This package also merges the parent- and nest-domains forecasts onto one combined domain grid. Information on how to acquire and build the UPP code is available in section 2. Please refer to the UPP Users’ Guide (http://www.dtcenter.org/upp/users/docs/user_guide/V3/upp_users_guide.pdf) for more details.

There are two main executables in UPP, unipost.exe and copygb.exe. This chapter covers only the module that calls unipost.exe. The use of copygb.exe is covered in Chapter 11.

10.2 Scripts

The postprocessing using UPP is run using two wrappers, unpost_wrapper and post_wrapper. These wrappers call the exhwrf_unpost.py and exhwrf_post.py scripts, respectively.
10. HWRF Post-Processor

10.2.1 Overview of exhwrf_unpost.py

The purpose of this script is to delete output from any previous attempt to run the same cycle.

1. Initialize the objects used to run all components of HWRF by calling `hwrf_expt.init_module()`.
2. Run the unrun modules for the following tasks:
   - runwrf
   - wrfcopier
   - satpost
   - nonsatpost
   - gribber

10.2.2 Overview of exhwrf_post.py

The Python script contains a loop that continually checks the status of the forecast, and postprocesses any output files that are available. As long as there are tasks remaining, it runs copies of `wrfcopier`, `nonsatpost`, and `satpost`. Note that `satpost` refers to the postprocessing to produce synthetic satellite brightness temperatures, while `nonsatpost` refers to the postprocessing of all other variables (temperature, winds, etc.).

10.2.3 Overview of UPP Python Modules

Wrfcopier  

Wrfcopier is a WRFCopyTask class object that lives in `ush/hwrf/copywrf.py`. It serves the primary purpose of delivering files from the WRF run directory to the `com/` directory.

Nonsatpost and Satpost  

Nonsatpost and satpost are PostManyWRF class objects that run the UPP on the WRF output files. They are used to produce general forecast products and synthetic satellite images, respectively. The run module for these tasks performs the following duties:

1. Link the input file (wrfout forecast or analysis file)
2. Make a control file that corresponds to the input file
3. Write `itag` file which contains the following four lines to be read by `unipost.exe`
   - Name of the WRF output file to be postprocessed
   - Format of the WRF output (NetCDF or binary; choose NetCDF for HWRF)
   - Forecast valid time (not model start time) in WRF format
10. HWRF Post-Processor

- Model name (NMM or NCAR; choose NMM for HWRF)

4. Run `unipost.exe`

**Output files:**

In the `intercom/` directory, there are directories for each forecast hour containing the satpost and nonsatpost output. The following list describes the naming convention for these directories and files. The forecast hour, `hh`, by default is hourly for the first nine hours, and three hourly after that for nonsatpost output and six-hourly for satpost output.

```plaintext
satpost-fhh00m/satpost-fhh00m/
    satpost-fhh00m-moad.egrb
    satpost-fhh00m-stormlinner.egrb
    satpost-fhh00m-stormlouter.egrb
nonsatpost-fhh00m/nonsatpost-fhh00m/
    nonsatpost-fhh00m-moad.egrb
    nonsatpost-fhh00m-stormlinner.egrb
    nonsatpost-fhh00m-stormlouter.egrb
```

**Status check:**

The string "INFO: completed post" will appear in the standard output file.

**Executables:**

`unipost.exe`

**FUNCTION:** Destaggers the HWRF native output, interpolates it vertically to pressure levels, computes derived variables, and outputs results in GRIB format.

**INPUT:**

- `hwrf_eta_micro_lookup.dat`
- `wrfout_d01, wrfout_d02 or wrfout_d03` - HWRF native output
- `itag - namelist`

**OUTPUT:**

- `unipost control file:`
- `for nonsatpost: hwrf_cntrl.nonsat; and,`
- `for satpost:hwrf_cntrl.sat${BASIN}, where BASIN can be A, B, L, E, C, P, Q, S, or W for Arabian Sea (Indian Ocean), Bay of Bengal (Indian Ocean), N. Atlantic, E. N. Pacific, Central N. Pacific, S. Indian Ocean, S. Atlantic, S. Pacific, or W. N. Pacific, respectively.`

**OUTPUT:**

- HWRF postprocessed output in GRIB format

**USAGE:**

```
unipost.exe < itag
```
11.1 Introduction

HWRF v3.7a will produce several types of forecast products, including processed GRIB1 and GRIB2 files (projected to lat-lon grids), track files, rainfall swath data, and wind products containing information about the tropical cyclone. The processed GRIB2 files are produced on several different grids outlined in Figure 11.1 for the general atmospheric fields and Figure 11.2 for satellite-derived products. Those GRIB1 files are used as input to the GFDL Vortex Tracker. Any of the GRIB output can also be used to create images with visualization packages such as GrADS, NCL, etc. Image generation is not covered in this Users’ Guide. Additionally, several files produced in the previous steps of a HWRF run (such as data assimilation and vortex relocation) are copied to the com directory to compose a full set of HWRF products.

The GFDL vortex tracker is a program that ingests model forecasts in GRIB format, objectively analyzes the data to provide an estimate of the vortex center position (latitude and longitude), and tracks the storm for the duration of the forecast. Additionally, it reports metrics of the forecast storm, such as intensity (maximum 10-m winds and MSLP) and structure (wind radii for 34-, 50-, and 64-knot thresholds in each quadrant of the storm) at each output time. The GFDL vortex tracker requires the forecast grids to be on a cylindrical equidistant, latitude-longitude (lat/lon) grid. For HWRF, UPP is used to process the raw model output and create the GRIB files for the tracker.

The vortex tracker creates two output files containing the vortex position, intensity, and structure information: one in Automated Tropical Cyclone Forecast (ATCF) format; and another in a modified ATCF format. See section 11.2.1 for the HWRF-specific naming conventions of these files.
Figure 11.1: Naming convention, resolution, and size for the output grids that contain conventional atmospheric data. Blue boxes indicate the grids from the wrfout files. Green boxes are the grids in the final GRIB files.

The GFDL vortex tracker locates the hurricane vortex center positions by searching for the average of the maximum or minimum of several parameters in the vicinity of an input first-guess position of the targeted vortex. The primary tracking parameters are relative vorticity at 850 hPa and 700 hPa, MSLP, and geopotential height at 850 and 700 hPa. Secondarily, wind speed at 10 m, 850 hPa, and 700 hPa are used. Winds at 500 hPa are used, together with other parameters, for advecting the storm and creating a first-guess position for all times beyond initialization. Many parameters are used to provide more accurate position estimates for weaker storms, which often have poorly defined structures/centers.

Besides the forecast file in GRIB format, the vortex tracker also ingests a GRIB index file, which is generated by running the program grbindex. The utility wgrib is also used for preparing data for the tracker. Both grbindex and wgrib were developed by NCEP and are distributed by the DTC as part of the HWRF Utilities.

This version of the tracker contains added capabilities of tracking cyclogenesis and identifying cyclone thermodynamic phases. The identification of cyclone thermodynamic phases requires that the input data contain temperature every 50 hPa from 300 to 500 hPa (for the Vitart scheme) or the geopotential height every 50 hPa from 300 to 900 hPa (for the Cyclone Phase Space scheme).

11.2 Scripts

The forecasts products are obtained by running the products_wrapper, which calls scripts/exhwrf_products.py after setting a few environment variables to redirect the
11. Forecast Products

Figure 11.2: Naming convention, resolution, and size for the output grids that contain satellite-derived products. Blue boxes indicate the grids from the wrfout files. Green boxes are the grids in the final GRIB files.

standard output and standard error files. These files can be placed anywhere by changing the environment variables REGRIBBER_LOGS and TRACKER_LOGS to the desired path.

The GFDL Vortex Tracker is driven by the wrapper script tracker_wrapper, which calls scripts/exhwrf_products.py. The Python script runs the tracker on the processed GRIB forecast files.

11.2.1 Overview of exhwrf_products.py

1. Initialize the objects used to run all components of HWRF by calling hwrf_expt.init_module()
2. Launch the four parallel tasks. The parent process launches products, while the subprocesses run copies of gribber and tracker. Each of these continually check the availability of files before running.
3. Deliver products to com/ directory as they become available from the products, gribber, tracker and other processes.

Files delivered to com/YYYYMMDDHH/STORMID directory:

The following examples are for Hurricane Gonzalo (2014), which was AL storm number 08. The string "gonzalo08" would be replaced by the name and number of the storm in the given experiment. SID is the storm ID (i.e., 08L for Gonzalo). The "I" or "L" following "gonzalo08" is a product of an operational naming convention requiring some files to have identical counterparts, but different capitalization. In this case, the letter "L" denotes
that the files are being delivered for a storm in the AL. Upper case YYYYMMDDHH denotes analysis time, while lower case yyyymmddhh denotes forecast time.

Index file for hwfrtrk
WRF namelist
11. Forecast Products

Products is a module that calls an NHCProducts object, whose run module lives in `ush/hwrf/nhc_products.py`, and is responsible for the following tasks:

1. Make namelist `products.nml`
2. Link the input files
3. Run `nhc_products.exe`
4. Deliver output

**Executables:**

`nhc_products.exe` This executable performs several functions.
II. Forecast Products

INPUT

1. wrfdiag_d0* files
2. Products namelist
3. Tcvitals
4. WRF hifreq output
5. ATCF file

OUTPUT

1. Swath file
2. Modified track file for TPC
3. Ascii wind and rainfall
4. Modified hifreq output from d03
5. File for NHC showing track position, heading and storm speed

Output files:

An example for Hurricane Gonzalo (2014):

gonzalo08L.YYYYMMDDHH.wind10hrly.ascii
gonzalo08L.YYYYMMDDHH.rainfall.ascii
gonzalo08L.YYYYMMDDHH.wind10m.ascii
gonzalo08L.YYYYMMDDHH.afos
GONZALO08L.YYYYMMDDHH.afos
GONZALO08L.YYYYMMDDHH.stats.tpc
GONZALO08L.YYYYMMDDHH.hwrfd03.htcf

Status Check:

The string "WARNING: No subtasks incomplete. I think I am done running. Will exit regribber now." will appear in each of the products standard out files.

Gribber ————————————

The Gribber is a GRIBTask object whose run module resides in ush/hwrf/gribtask.py. Its primary function is to run copygb.exe to horizontally interpolate the native UPP output files to a variety of regular lat/lon grids.

Output files:

The following sets of files get delivered to the intercom/regribber:

hwrftrk.YYYYMMDD.HH0000
hwrftrk.YYYYMMDD.HH0000.grbindex
hwrftrkd01.YYYYMMDD.HH0000
hwrftrkd01.YYYYMMDD.HH0000.grbindex
11. Forecast Products

hwrftrkd02.YYYYMMDD.HH0000
hwrftrkd02.YYYYMMDD.HH0000.grbindex
parenthigh.YYYYMMDD.HH0000
trkbasic.YYYYMMDD.HH0000

Status Check:

The string "INFO: storm1: completed regribbing job for" will appear in each of the POST standard output files, which will be set by the environment variable REGRIBBER_LOGS in the products_wrapper.

Executables:

copygb.exe

This executable performs two functions. The functions are separated in the explanation by their respective numeric items.

FUNCTION:

1. Interpolates a GRIB file to a user-specified grid
2. Combines two GRIB files

INPUT:

1. ${hr_grid} - User-specified grid
   One grib file, for example
2. ${hr_grid} - User-specified grid
   Two GRIB files, for example

OUTPUT: GRIB file on grid ${hr_grid}

USAGE:

1. copygb.exe -xg "${hr_grid}" input_GRIB_file \ out_GRIB_file
2. When an "-M" option is used and the argument following it is a GRIB file, the GRIB file will be interpreted as a merge file. This option can be used to combine two GRIB files.
   The following command will combine two GRIB files onto a a third one named out_GRIB_file. All three files must use a grid specified by ${hr_grid}.
   copygb.exe -g "${hr_grid}" -xM input_GRIB_file_1 \ input_GRIB_file_2 out_GRIB_file
The TrackerTask is responsible for running the GFDL Vortex Tracker. The tracker reads the HWRF postprocessed files in the combined domain. It produces a 3-hourly track and a 6-hourly track for the entire forecast length, as well as another track for the 12-hr forecast (stripped down version of gonzalo08l.YYYYMMDDHH.trak.hwrf.atcfunix file), using a merged grid from all three domains with 0.02° resolution. The track for the 12-hr forecast is used in the vortex relocation procedure for the following cycle. The tracker module resides in ush/hwrf/tracker.py and performs the following actions:

1. Link the input GRIB files
2. Make the tracker namelist
3. Run hwrf_gettrk.exe
4. Deliver files

Output files:

The following output files are an example for Hurricane Gonzalo (2014).

```
gonzalo08l.YYYYMMDDHH.trak.hwrf.raw
gonzalo08l.YYYYMMDDHH.trak.hwrf.atcfunix
gonzalo08l.YYYYMMDDHH.trak.hwrf.3hourly
gonzalo08l.YYYYMMDDHH.trak.hwrf.short6hr
```

Similar outputs are also generated from d01 and d02 domains with 0.1° and 0.06° resolution.

Status Check:

The standard output file will contain the string "CRITICAL: Successful return status from gettrk."

Executables:

```
 hwrf_gettrk.exe
```

FUNCTION: Runs the GFDL Vortex Tracker

**INPUT:**
- `fort.11` - GRIB file containing the postprocessed HWRF forecast
- `fort.12` - TC Vitals file containing the first guess location of the forecast vortex
- `fort.14` - TC Vitals file used for tropical cyclogenesis tracking. This file is not used in HWRF’s operational configuration. File fort.14, which can be blank, should exist in the directory where the tracker is run, otherwise the tracker will stop.
- `fort.15` - Forecast lead times (in minutes) the tracker will process
- `fort.31` - a GRIB index file generated by the program grbindex
- `input.namelist` - namelist
11. Forecast Products

OUTPUT:

- \texttt{fort.69} – Modified ATCF file
- \texttt{fort.64} – Modified ATCF file
- \texttt{fort.66} – Modified ATCF file produced only in "cyclogenesis mode"
- \texttt{fort.74} – Modified ATCF file produced when IKEFLAY=Y

USAGE: \texttt{hwrf_gettrk.exe <namelist}}

Refer to Appendix C for a sample namelist and an explanation of contents of output files.

11.2.2 Additional Tracking Utilities

In addition to the actual tracking capability of the GFDL Vortex Tracker, the HWRF wrapper and Phyton scripts also automatically generate phase space diagnostics. Just for reference, the section below explains the steps to compute phase space diagnostics.

Phase-Space Diagnostics ————————————

1. In the GFDL vortex tracker namelist set the items listed below:
   \begin{itemize}
   \item phaseflag=y
   \item phasescheme=both or cps or vtt
   \item wcore_depth=1.0
   \end{itemize}

2. If phasescheme is set to cps, run \texttt{hwrf_vint.exe} to vertically interpolate the geopotential from 300 to 900 hPa at a 50-hPa interval. Then append these geopotential variables to the tracker’s GRIB format input file.

3. If phasescheme is set to vtt, run \texttt{hwrf_vint.exe} to vertically interpolate the temperature from 300 to 500 hPa at a 50-hPa interval. Then run \texttt{hwrf_tave.exe} to obtain the average temperature between 300 and 500 hPa. This average temperature field is appended to the tracker’s GRIB format input file.

4. If phasescheme is set to both, then both steps 2) and 3) are needed.

5. When the phase-space diagnostics is performed, the output will be generated in \texttt{fort.64} as fields 37-41.

Executables:

\texttt{hwrf_vint.exe}

FUNCTION: Interpolates from various pressure levels onto a regularly spaced grid, with 50-hPa vertical level intervals. Each run only processes one lead time. Therefore, it is necessary to use this executable separately for all lead times.
II. Forecast Products

INPUT:
- fort.11 – GRIB file containing the postprocessed HWRF output with temperature at least at 300 and 500 hPa.
- fort.16 – text file containing the number of input pressure levels.
- fort.31 – index file of fort.11
- namelist – generated by `echo "&timein ifcsthour=$fhour iparm=$gparm/" > namelist` where $fhour is the forecast lead time and $gparm is the variable to be processed. For phase space diagnostics, geopotential height (when phasescheme=cps, $gparm=7) or temperature (when phasescheme=vtt, $gparm=11) or both (when phasescheme=both) need to be processed.

OUTPUT:
- fort.51 – GRIB file that contains the temperature data on vertical levels 300, 350, 400, 450, and 500 hPa

USAGE: `hwrf_vint.exe < namelist`

hwrf_tave.exe

FUNCTION: Vertically averages temperature in the 500-300 hPa layer

INPUT:
- fort.11 – GRIB file containing the temperature at least at levels 300, 350, 400, 450, and 500 hPa. This file can be generated by `hwrf_vint.exe`
- fort.16 – text file containing the number of input pressure levels.
- fort.31 – index file of fort.11
- namelist – generated by the command `echo "&timein ifcsthour=$fhour, iparm=11/" > namelist`

OUTPUT:
- fort.51 – GRIB file containing the mean temperature in the 300-500 hPa layer.

USAGE: `hwrf_tave.exe < namelist`

Obtaining Phase-Space Diagnostics when Running in Tracker Mode

1. In the GFDL vortex tracker namelist set the items listed below:
   - `phaseflag=y`
   - `phasescheme=both` or `cps` or `vtt`
   - `wcore_depth=1.0`

2. If `phasescheme` is set to `cps`, run `hwrf_vint.exe` to vertically interpolate the geopotential from 300 to 900 hPa at a 50-hPa interval. Then append these geopotential variables to the tracker’s GRIB format input file.

3. If `phasescheme` is set to `vtt`, run `hwrf_vint.exe` to vertically interpolate the temperature from 300 to 500 hPa at a 50-hPa interval. Then run `hwrf_tave.exe` to
obtain the average temperature between 300 and 500 hPa. This average temperature field is appended to the tracker’s GRIB format input file.

4. If phasescheme is set to both, then both steps 2) and 3) are needed.
5. When the phase space diagnostics is performed, the output will be generated in fort.64 as fields 37-41 (see Appendix C).

11.3 How to Plot the Tracker Output Using ATCF_PLOT

The GFDL Vortex Tracker comes with atcf_plot, a set of GrADS scripts that can be used to plot hurricane track files in ATCF format. These scripts can be found in the directory: gfdl-vortextracker/trk_plot/plottrak.

To use atcf_plot to plot the storm’s track, perform the following steps:

• Enter the directory gfdl-vortextracker/trk_plot.
• Run gribmap on the GrADS ctl file plottrak.ctl by typing: gribmap -v -i plottrak.ctl. gribmap is a GrADS utility that maps the contents of the binary data using the ctl file. It creates a map (plottrak.ix) that points to the locations where the requested binary data start for the different variables and levels.

You should see one line in the output that has "MATCH" in the string. Both the plottrack.ctl and the newly created plottrak.ix map file need to be in the directory where the script below is run:

• Edit the atcfplot.sh to set the following paths:
  1. gradsv2 – path to the GrADS executable (for example, /contrib/grads/bin/gradsc)
  2. GADDIR – path to the directory containing the supplemental font and map files in for GrADS (for example, /contrib/grads/lib)
  3. scrdir – path to the working directory (for example, ${SCRATCH}/sorc/gfdl-vortextracker/trk_plot/plottrak)
  4. plotdir – path to the directory where the plot files will be created (for example, ${SCRATCH}/sorc/gfdl-vortextracker/trk_plot/plottrak/tracks)
• Edit atcfplot.gs to define the following paths:
  1. rundir – same as scrdir in atcfplot.sh (note rundir must end with a "/")
  2. netdir – same as plotdir in atcfplot.sh (note netdir must end with a "/")
  3. Change all instances of HTUT to HCOM
• Edit get_mods.sh to define the following paths:
  1. rundir – same as scrdir in atcfplot.sh
  2. netdir – same as plotdir in atcfplot.sh
  3. ndate – path to the script ndate.ksh
  4. nhour – path to the script nhour.ksh
• Edit get_verif.sh to define the following paths:
  1. rundir – same as scrdir in atcfplot.sh
  2. netdir – same as plotdir in atcfplot.sh
  3. ndate – path to the script ndate.ksh

125
II. Forecast Products

4. nhour – path to the script nhour.ksh

• The users need to insert or append their vortex tracker output, fort.64, into the file aBASIN|SID|YYYY.dat. The following two commands are an example of how to do this for Hurricane Gonzalo a-deck files:
  
  sed -i 's/HWRF/HCOM/g' $COMhwrf/YYYYMMDDHH/08L/aa1082014_HWRF_hPYHW YYYYMMDDHH.dat
  cat $COMhwrf/YYYYMMDDHH/08L/aa1082014_HWRF_hPYHW YYYYMMDDHH.dat aal082014.dat

• After setting up the paths to the correct locations in your system, run the script using the following command:
  
  atcfplot.sh YYYY BASIN

This will start a GUI window and read in ATCF format track files a${BASIN}${SID}${YYYY}.dat in $rundir.

For example, the user can use the command atcfplot.sh 2011 al to plot the track files aal${SID}2011.dat in $rundir.

When the GUI window appears, from the drop down menu, select a storm, start date, and a model name ("atcfname" in the GFDL vortex tracker namelist), then click the "Plot" button to plot the track. The plots can be exported to image files by using the "Main" and then "Print" menu options. The default tracker namelist is set to use the ATCF model name "HCOM". If the user changes this name in the tracker namelist, the ATCF_PLOT GUI will not recognize the new name. In this case, the user needs to replace an unused atcfname with the new atcfname. The atcfnames in the GUI can be found by searching in function "modnames" in atcfplot.gs. Note all three instances of the unused atcfname need to be replaced in atcfplot.gs.

For example, if "USER" was employed as the ATCF model name in the users’ GFDL Vortex Tracker output fort.64, atcfplot.gs needs to be modified to have the ATCF_PLOT program GUI interface show a button for the atcfname "USER". To do that, open atcfplot.gs, go to function "modnames", find an atcfname that will not be used, for example "HCOM", and manually replace the string "HCOM" with "USER".
12

HWRF Idealized Tropical Cyclone Simulation

12.1 Introduction

Initial conditions for the HWRF Idealized Tropical Cyclone case are specified using an idealized vortex superposed on a base-state quiescent sounding. The default initial vortex has an intensity of $20 \text{ ms}^{-1}$ and a radius of maximum winds of 90 km. To initialize the idealized vortex, a nonlinear balance equation in pressure-based sigma coordinates is solved within the rotated latitude-longitude E-grid framework.

The default initial ambient base state assumes an f-plane at the latitude of $12.5^\circ$. The sea surface temperature is time-invariant and horizontally homogeneous, with the default set to 302 K. No land is used in the simulation domain.

The lateral boundary conditions used in the HWRF idealized simulation are the same as used in real data cases. This inevitably leads to some reflection when gravity waves emanating from the vortex reach the outer domain lateral boundaries.

The idealized simulation uses the operational HWRF triple-nested domain configuration with grid spacing at 18, 6, and 2 km. All the operational atmospheric physics, as well as the supported experimental physics options in HWRF, can be used in the idealized HWRF framework. The UPP (see Chapter 10) can be used to postprocess the idealized HWRF simulation output. The HWRF Python scripts are not suitable to run...
the idealized simulation. Therefore, the user should refer to the DTC UPP website at http://www.dtcenter.org/upp/users and to the UPP User’s Guide at http://www.dtcenter.org/upp/users/docs/user_guide/V3/upp_users_guide.pdf for more information on how to run UPP for the idealized HWRF simulation.

The setup of the idealized simulation requires the use of WPS to localize the domain (geogrid.exe) and to process GFS data for initial and boundary conditions (ungrib.exe and metgrid.exe). The initialization using WPS just provides a framework for the initial conditions, which are actually specified in ideal.exe to be composed of a quiescent environment with a prescribed vortex. The boundary conditions generated with WPS are also overwritten by ideal.exe to be consistent with the quiescent environment.

The initial base-state temperature and humidity profile is prescribed in file sound.d, while the vortex properties are specified in input.d. The latter file is also used to specify options for f-plane and β-plane.

12. How to Use HWRF for Idealized Tropical Cyclone Simulations

12.2 Source Code

This section describes the process to implement HWRF v3.7a in the idealized setting. Only the WPS and WRFV3 components are required for the idealized tropical cyclone simulations. The UPP can be used for postprocessing. The other HWRF components do not need to be compiled. Please see Chapter 2 for instructions to compile the WPS, WRF, and, if desired, UPP. Note that the executable file wrf.exe needed for the idealized simulation is not the same as the one needed for the simulation for real data. Therefore, users should follow the instructions specific for building the idealized wrf.exe. In this Users’ Guide, we assume that the user will install HWRF in directory ${SCRATCH}/hwrfrun.

12.2.2 Input Files and Datasets

Two GFS GRIB files are needed to provide a template for creating the initial and lateral boundary conditions. One of the GFS GRIB files should be the analysis valid at the same time of the desired HWRF initialization. The other GRIB file should be a forecast, with lead time equal to or greater than the desired HWRF simulation. The meteorological data in these files will not be used to initialize the simulation – these files are for template purposes only.

As an example, files gfs.t12z.pgrb2.0p25.f000 and gfs.t12z.pgrb2.0p25.f120, are included in the tar file http://www.dtcenter.org/HurrWRF/users/downloads/datasets/Idealized_2015/hwrfv3.7a_idealized.tar.gz.

Next the user must ensure that all the input files below exist in

12. HWRF Idealized Tropical Cyclone Simulation

Namelist file for WPS; Note that geog_data_path should be modified to point to the actual path of the geog data files.

Namelist file for WRF

Vortex description file

Sounding data; four sounding files (sound.d, sound_gfdl.d, sound_jordan.d, and sound_wet.d) are provided in $(SCRATCH)/hwrfrun/sorc/WRFV3/test/nmm_tropical_cyclone, however, only the one named sound.d will be used. To use a different sounding, rename it to sound.d.

Vortex center file

Sigma file

12.2.3 General Instructions for Running the Executables

To perform the idealized simulation the following executables need to be run: geogrid.exe, ungrib.exe, mod_levels.exe, metgrid.exe, ideal.exe, and wrf.exe. Since the executables are compiled with distributed memory capability, many computing platforms require they be run on compute nodes. Instructions for running jobs on compute nodes can be found in section 3.5.1.

The wrappers and Python scripts described in previous chapters for running HWRF using real data are not used for the idealized simulation. Since the workflow of the idealized simulation is fairly simple, the commands can be run manually.

12.2.4 Running WPS to Create the ICs and LBCs

The steps below outline the procedure to preprocess the data for the creation of initial and boundary conditions for the idealized simulation. It assumes that the run will be conducted in a working directory named $WORKDIR/wpsprd.

1. Create and change into directory for running WPS:
   
   mkdir $WORKDIR/wpsprd
   cd $WORKDIR/wpsprd

2. Run geogrid
   
   a) Copy the WPS namelist.
      
      cp $(SCRATCH)/hwrfrun/sorc/WRFV3/test/
      nmm_tropical_cyclone/namelist.wps.
   
   b) Edit namelist.wps to make sure geog_data_path points to the location of the WPS geographical data files, which are included in the fix tarball in the fix/hwrfrun/sorc/WPSV3/geogrid.
   
   c) Link the geogrid table.
      
      ln -fs $(SCRATCH)/hwrfrun/sorc/WPSV3/geogrid/
      GEOGRID.TBL.NMM ./GEOGRID.TBL
12. HWRF Idealized Tropical Cyclone Simulation

   d) Run executable `geogrid.exe` on the command line or submit it to a compute node or batch system.
      
      ```
      ${SCRATCH}/hwrfrun/sorc/WPSV3/geogrid.exe
      ```
   
   e) Verify that the output files were created.
      
      ```
      ls -l geo_nmm_nest.10[12].nc geo_nmm.d01.nc
      ```

3. Run ungrib

   a) Link the ungrib table.
      
      ```
      ln -fs ${SCRATCH}/hwrfrun/sorc/WPSV3/ungrib/Variable_Tables/Vtable.GFS ./Vtable
      ```
   
   b) Extract the two input GFS files.
      
      
      ```
      tar -xzvf hwrfv3.7a_idealized.tar.gz
gunzip gfs.t12z.pgrb2.0p25.f000.gz
gunzip gfs.t12z.pgrb2.0p25.f120.gz
      ```
      
      ```
      ls -l gfs.t12z.pgrb2.0p25.f000 gfs.t12z.pgrb2.0p25.f120
      ```
   
   c) Link the GFS files to the names expected by ungrib.
      
      ```
      ${SCRATCH}/hwrfrun/sorc/WPSV3/link_grib.csh \
gfs.t12z.pgrb2.0p25.f000 gfs.t12z.pgrb2.0p25.f120
      ```
   
   d) Run executable `ungrib.exe` on the command line or submit it to a compute node or batch system.
      
      ```
      ${SCRATCH}/hwrfrun/sorc/WPSV3/ungrib.exe
      ```
   
   e) Verify that the output files were created.
      
      ```
      ls -l GFS:2012-10-26_12 GFS:2012-10-31_12
      ```

4. Run metgrid

   a) Link the metgrid table.
      
      ```
      ln -fs ${SCRATCH}/hwrfrun/sorc/WPSV3/metgrid/\METGRID.TBL.NMM ./METGRID.TBL
      ```
   
   b) Run executable `mod_levels.exe` twice on the command line or submit it to a compute node or batch system. This program is used to reduce the number of vertical levels in the GFS file. Only the levels listed in variable `press_pa` in `namelist.wps` will be retained.
      
      ```
      ${SCRATCH}/hwrfrun/sorc/WPSV3/util/mod_levs.exe \
GFS:2012-10-26_12 new_GFS:2012-10-26_12
${SCRATCH}/hwrfrun/sorc/WPSV3/util/mod_levs.exe \
GFS:2012-10-31_12 new_GFS:2012-10-31_12
      ```
   
   c) Verify that the output files were created.
      
      ```
      ls -l new_GFS:2012-10-26_12 new_GFS:2012-10-31_12
      ```
   
   d) Run executable `metgrid.exe` on the command line or submit it to a compute node or batch system.
      
      ```
      ${SCRATCH}/hwrfrun/sorc/WPSV3/metgrid.exe
      ```
   
   e) Verify that the output files were created.
      
      ```
      ls -l met_nmm.d01.2012-10-26_12_00_00.nc \nmet_nmm.d01.2012-10-31_12_00_00.nc
      ```
12. **HWRF Idealized Tropical Cyclone Simulation**

12.2.5 **Running ideal.exe and wrf.exe**

The steps below outline the procedure to create initial and boundary conditions for the idealized simulation. It assumes that the run will be conducted in a working directory named `$WORKDIR/wrfprd`.

1. Create and change into directory for running ideal and real.
   ```bash
   mkdir $WORKDIR/wrfprd
   cd $WORKDIR/wrfprd
   ``
2. Run ideal
   a) Link WRF input files.
      ```bash
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/ETAMPNEW_DATA .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/ETAMPNEW_DATA.expanded_rain .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/GENP ARM.TBL .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/LANDUSE.TBL .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/SOILP ARM.TBL .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/VEGPARM.TBL .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/tr49t67 .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/tr49t85 .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/tr67t85 .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/ozone.formatted .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/ozone_lat.formatted .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/ozone_plev.formatted .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/RRTM_DATA .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/RRTMG_LW_DATA .
      ln -fs ${SCRATCH}/hwrfrun/sorc/WRFV3/run/RRTMG_SW_DATA .
   
   b) Link the WPS input files.
      ```bash
      ln -fs $WORKDIR/wpsprd/met_nmm* .
      ln -fs $WORKDIR/wpsprd/geo_nmm* .
   
   c) Copy the idealized simulation input files.
      ```bash
      cp ${SCRATCH}/hwrfrun/sorc/WRFV3/test/\nmm_tropical_cyclone/input.d .
      cp ${SCRATCH}/hwrfrun/sorc/WRFV3/test/\nmm_tropical_cyclone/sigma.d .
      cp ${SCRATCH}/hwrfrun/sorc/WRFV3/test/\nmm_tropical_cyclone/sound.d .
   
   d) Copy namelist input.
      ```bash
      cp ${SCRATCH}/hwrfrun/sorc/WRFV3/test/\nmm_tropical_cyclone/namelist.input .
      
   e) Edit and modify files `input.d`, `sound.d`, if desired.
      ```bash
      • The sounding files provided have 30 vertical levels. To use a sounding
        with different number of levels, it is necessary to modify the source code 
        ln ${SCRATCH}/hwrfrun/sorc/WRFV3/dyn_nmm/\n   ```
module_initialize_tropical_cyclone.F. In subroutine tem, parameter nv should be modified from 30 to the number of levels in the sounding.

- File storm.center should not be altered to make sure the storm is located in the center of the inner nest.
- File sigma.d should not be modified as it does not pertain to the vertical levels of the sounding or of the simulation. Rather, it defines the vertical levels used to create the initial vortex.

f) Run executable ideal.exe on the command line or submit it to a compute node or batch system.

```
$(SCRATCH)/hwrfrun/sorc/WRFV3/main/ideal.exe
```

g) Verify that the output files were created.

```
ls -l wrfinput_d01 wrfbdy_d01 fort.65
```

3. Run WRF

a) Run executable wrf.exe on the command line or submit it to a compute node or batch system.

```
$(SCRATCH)/hwrfrun/sorc/WRFV3/main/wrf.exe
```

Note that executable wrf.exe must have been created using the instructions for idealized simulations described in Chapter 2. The executable created for regular HWRF simulations that ingest real data should not be used to conduct idealized simulations.

b) Verify that the output files were created.

```
ls -l wrfout_d01* wrfout_d02* wrfout_d03*
```
Example of Computational Resources

Table A.1 gives an example of the resources required to run HWRF compiled with Intel in operations on the NOAA Research Supercomputer Jet and should be used as a guideline for scaling to the resources at the individual user’s disposal. In the example below, the available resources include access to 5440 cores with 16 2.6 GHz cores per node. Each node has 32 GB (2 GB per core). With peak performance capable of 113.2 TF, and end-to-end run of HWRF would take about four hours.

Additional GFDL Tracker

Sample namelist

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inp%bcc</td>
<td>First two digits of the year for the initial time of the forecast (e.g., the &quot;20&quot; in &quot;2012&quot;).</td>
</tr>
<tr>
<td>inp%byy</td>
<td>Last two digits of the year for the initial time of the forecast (e.g., the &quot;12&quot; in &quot;2012&quot;).</td>
</tr>
<tr>
<td>inp%bmm</td>
<td>Two-digit month (01, 02, etc) for the initial time of the forecast.</td>
</tr>
<tr>
<td>inp%bdd</td>
<td>Two-digit day for the initial time of the forecast.</td>
</tr>
<tr>
<td>inp%bhh</td>
<td>Two-digit hour for the initial time of the forecast.</td>
</tr>
<tr>
<td>inp%model</td>
<td>Model ID number as defined by the user in the script. This is used in subroutine getdata to define what the GRIB IDs are for surface wind levels. Create a unique number in the script for your model and make sure you have the corresponding IDs set up for it in subroutine getdata. For HWRF use 17. The Model ID numbers for other models are listed below:</td>
</tr>
</tbody>
</table>

### C. Additional GFDL Tracker Information

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inp%modtyp</td>
<td>Type of the model. Either &quot;global&quot; or &quot;regional&quot;. For HWRF, choose &quot;regional&quot;.</td>
</tr>
<tr>
<td>inp%lt_units</td>
<td>&quot;hours&quot; or &quot;minutes&quot;, this defines the lead time unit used by the PDS in your GRIB header.</td>
</tr>
<tr>
<td>inp%file_seq</td>
<td>&quot;onebig&quot; or &quot;multi&quot;, this specifies if the tracker will process one big input file or multiple files for each individual lead times. &quot;onebig&quot; is used as the default method in the community HWRF scripts.</td>
</tr>
<tr>
<td>inp%nesttyp</td>
<td>Type of the nest grid. Either &quot;moveable&quot; or &quot;fixed&quot;. For HWRF, choose &quot;moveable&quot;.</td>
</tr>
<tr>
<td>atcfnum</td>
<td>Obsolete; can be set to any integer.</td>
</tr>
<tr>
<td>atcfname</td>
<td>Character model ID that will appear in the ATCF output (e.g., GFSO, HWRF, AHW, HCOM etc).</td>
</tr>
<tr>
<td>atcfymdh</td>
<td>10-digit yyyyymmddhh date that will be used in output text track files.</td>
</tr>
<tr>
<td>atcffreq</td>
<td>Frequency (in centahours) of output for atcfunix. Default value is 600 (six hourly).</td>
</tr>
<tr>
<td>trkrinfo%type</td>
<td>Defines the type of tracking to do. A &quot;tracker&quot; run functions as the standard TC tracker and tracks only storms from the TC Vitals. &quot;tcgen&quot; and &quot;midlat&quot; run in genesis mode and will look for new storms in addition to tracking from TC Vitals. &quot;tcgen&quot; will look for all parameters at the various vertical levels, while &quot;midlat&quot; will only look for MSLP and no checks are performed to differentiate tropical from non-tropical cyclones. For HWRF, choose &quot;tracker&quot;.</td>
</tr>
<tr>
<td>trkrinfo%mslpthresh</td>
<td>Threshold for the minimum MSLP gradient (units hPa/km) that must be met to continue tracking.</td>
</tr>
<tr>
<td>trkrinfo%v850thresh</td>
<td>Threshold for the minimum azimuthally-average 850 hPa cyclonic tangential wind speed (m/s) that must be exceeded in order to keep tracking.</td>
</tr>
<tr>
<td>trkrinfo%gridtype</td>
<td>&quot;global&quot; or &quot;regional&quot;, this defines the type of domain grid. For HWRF or other limited area models, choose &quot;regional&quot;.</td>
</tr>
<tr>
<td>trkrinfo%contint</td>
<td>This specifies the interval (in Pa) used by subroutine check_closed_contour to check for a closed contour in the mslp field when running in genesis mode. Note that check_closed_contour is also called from the routine that checks for a warm core, but the contour interval is hard-wired in the executable as 1.0 degree K for that usage.</td>
</tr>
<tr>
<td>trkrinfo%out_vit</td>
<td>This is only set to &quot;y&quot; if the tracker is running in genesis mode, and it tells the tracker to write out a &quot;TC Vitals&quot; record for any storms that it finds at the model initialization time. For HWRF, choose &quot;n&quot;.</td>
</tr>
<tr>
<td>trkrinfo%g2_jpdtn</td>
<td>This is set to zero if trying to read deterministic model data, and 1 if trying to read ensemble model data.</td>
</tr>
<tr>
<td>trkrinfo%gribver</td>
<td>This is set to 1 if reading GRIBI files. This is the only version supported with HWRF v3.7a.</td>
</tr>
<tr>
<td>trkrinfo%westbd</td>
<td>For genesis runs, the western boundary for searching for new storms. Does not need to match the boundaries of your grid, it can be smaller.</td>
</tr>
</tbody>
</table>
### C. Additional GFDL Tracker Information

**trkrinfo%eastbd**
For genesis runs, the eastern boundary for searching for new storms. Does not need to match the boundaries of your grid, it can be smaller than your grid.

**trkrinfo%northbd**
For genesis runs, the northern boundary for searching for new storms. Does not need to match the boundaries of your grid, it can be smaller than your grid.

**trkrinfo%southbd**
For genesis runs, the southern boundary for searching for new storms. Does not need to match the boundaries of your grid, it can be smaller than your grid.

**phase**
phase/uniFb02
"y" or "n", tells the program whether or not to determine the cyclone thermodynamic phase.

**phasescheme**
phasescheme "cps", "vtt", "both", tells the program which scheme to use for checking the cyclone phase. "cps" is Hart's cyclone phase space, "vtt" is a simple 300-500-hPa warm core check based on Vitart, and "both" tells the program to use both schemes. Not used if phaseflag="n".

**wcore_depth**
The contour interval (in deg K) used in determining if a closed contour exists in the 300-500-hPa temperature data, for use with the vtt scheme.

**structflag**
struct/uniFb02
"y" or "n", tells the program whether or not to determine the cyclone thermodynamic structure.

**ikeflag**
ike/uniFb02
"y" or "n", tells the program whether or not to calculate the Integrated Kinetic Energy (IKE) and Storm Surge Damage Potential (SDP).

**gmodname**
gmodname Define the model name in the input files, e.g., "hwrf". Only when inp%file_seq="multi".

**rundescr**
rundescr Describes the model runs in the input files, e.g., "combined". Only when inp%file_seq="multi".

**atcfdescr**
atcfdescr Describe the storm information in the input files, e.g., "irene09l". Only when inp%file_seq="multi".

**verb**
verb Level of detail printed to terminal. Choose from 0 (no output), 1 (error messages only), 2 (more messages), 3 (all messages).

**use_waitfor**
use_waitfor "y" or "n", for waiting for input files. Use "n" unless for real-time operational runs.

### Contents of the output files

```
C. Additional GFDL Tracker Information

| Column 1: basin name. "AL" represents Atlantic and "EP" northeast Pacific. |
| Column 2: ATCF storm ID number. Gonzalo was the 8th storm in the Atlantic Basin in 2014. |
| Column 3: model starting time. |
| Column 4: constant and 03 simply indicates that this record contains model forecast data. |
| Column 5: model ATCF name. |
| Column 6: forecast lead time in hours multiplied by 100 (e.g., 00900 represents 9.00 h). |
| Column 7–8: vortex center position (latitude and longitude multiplied by 10). |
| Column 9: vortex maximum 10-m wind (in kt). |
| Column 10: vortex minimum MSLP (in hPa). |
| Column 11: placeholder for character strings that indicate whether the storm is a depression, tropical storm, hurricane, subtropical storm etc. Currently, that storm type character string is only used for the observed storm data in the NHC Best Track data set. |
| Column 12: thresholds wind speed in knots, an identifier that indicates whether this record contains radii for the 34-, 50- or 64-knot wind thresholds. |
| Column 13: "NEQ" indicates that the four radii values that follow will begin in the northeast quadrant and progress clockwise. |
| Column 14–17: wind radii (in nm) for the threshold winds in each quadrant. |
| Column 18–19: not used. |
| Column 20: radius of maximum winds, in nautical miles. |

A sample of the vortex tracker output fort.64 is listed below:

```

Column 1–20: same as fort.69 except that column 6, the forecast lead time, instead of being a 5-digit integer as in fort.69, is a 3-digit integer.

Column 21–35: space fillers.

Column 36: "THERMO PARAMS" indicating that thermodynamics parameters will follow.
### C. Additional GFDL Tracker Information

Column 37–39: The three cyclone phase space parameters, and all values shown have been multiplied by a factor of 10. The values are listed below:

1. Parameter B (left-right thickness asymmetry)
2. Thermal wind (warm/cold core) value for lower troposphere (900–600 hPa)
3. Thermal wind value for upper troposphere (600–300 hPa)

Column 40: Presence of a warm core. In this sample it is "U", which stands for "undetermined", meaning the warm core check was not performed. When the warm core check is performed, this field will be either "Y" or "N", indicating whether the warm core is identified or not.

Column 41: Warm core strength x 10 (in degrees). It indicates the value of the contour interval that was used in performing the check for the warm core in the 300–500 hPa layer.

Column 42–43: Constant strings.

</tbody>
</table>

Column 1: "TG", the basin id for cyclogenesis (when trkrinfo%type is set to midlat, this id is named "ML").

Column 2: the number of cyclogenesis the tracker identified.

Column 3: the ID for the cyclogenesis, ${YYYYMMDDHH}_F${FFF}_$Lat_$Lon_FOF where YYYYMMDDHH, FFF, Lat and Lon are the model initialization time, the forecast lead time, the latitude and the longitude, respectively, in which the cyclogenesis was first identified.

Column 4–18: same as Columns 3–17 in **fort.64**.

Column 19: pressure of last closed isobar (in hPa).

Column 20: radius of last closed isobar (nm).

Column 21: radius of maximum wind (nm).
C. Additional GFDL Tracker Information

Column 22–24: The cyclone phase space parameters, and all values shown have been multiplied by a factor of 10. The values are listed below:

1. Parameter B (left-right thickness asymmetry)
2. Thermal wind (warm/cold core) value for lower troposphere (900–600 hPa)
3. Thermal wind value for upper troposphere (600–300 hPa)

Column 25: Presence of a warm core. In this sample it is "U", which stands for "undetermined", meaning the warm core check is not performed. When the warm core check is performed, this field will be either "Y" or "N", indicating whether the warm core is identified or not.

Column 26: storm moving direction (in degrees).
Column 27: storm moving speed (in tenths of ms⁻¹).
Column 28: mean 850-hPa vorticity (s⁻¹x10e5).
Column 29: max (gridpoint) 850-hPa vorticity (s⁻¹x10e5).
Column 30: mean 700 hPa vorticity (s⁻¹x10e5).
Column 31: max (gridpoint) 700 hPa vorticity (s⁻¹x10e5).

Column 1-11: Same as fort.64.
Column 12-13: fixed fields.
Column 14: wind damage potential (wdp) (not computed in this version, therefore is always zero).
Column 15: storm surge damage potential (SDP) (multiplied by 10).
Column 16-18: IKE, in terajoule, for 10 ms⁻¹, 18 ms⁻¹ and 33 ms⁻¹ winds, respectively.
Column 19-21: IKE for 25-40 ms⁻¹, 41-54 ms⁻¹ and 55 ms⁻¹ winds, currently not computed, therefore are always zero.
Column 22-23: vortex center position (latitude and longitude multiplied by 100).
