

CCPP Training

College Park, MD, March 12-13, 2019

Using GitHub with CCPP

Laurie Carson

Global Model Test Bed

Using GitHub with CCPP

- Overview (brief!) of git and GitHub
- Overview of GitHub workflow
- Code repositories and how to get the code

git: distributed version control systems

- This presentation (slides, and recorded video) has a nice history and background of VCS systems!

<https://www2.cisl.ucar.edu/user-support/training/library/using-git-centralized-and-distributed-version-control-workflows>

- All developers have a local copy of the entire project
- Everyone can work at their own pace and merge with the authoritative repository when convenient
- There are many web-based git repository hosts available:
 - GitHub.com
 - Vlab.ncep.noaa.gov
 - Bitbucket.org

GitHub features

- Organizations and individuals can manage and host repositories
- Public and private repositories
- Many add-on software engineering tools available
- NCAR provides a GitHub organizational space
 - Public and private repositories
 - NOAA-EMC, NOAA-GFDL, others also
- Individuals can create repositories
 - Free accounts can only create public repos
- Individual accounts can fork private repositories (to which they have access) and those retain the private status
- These features support a “forking” workflow

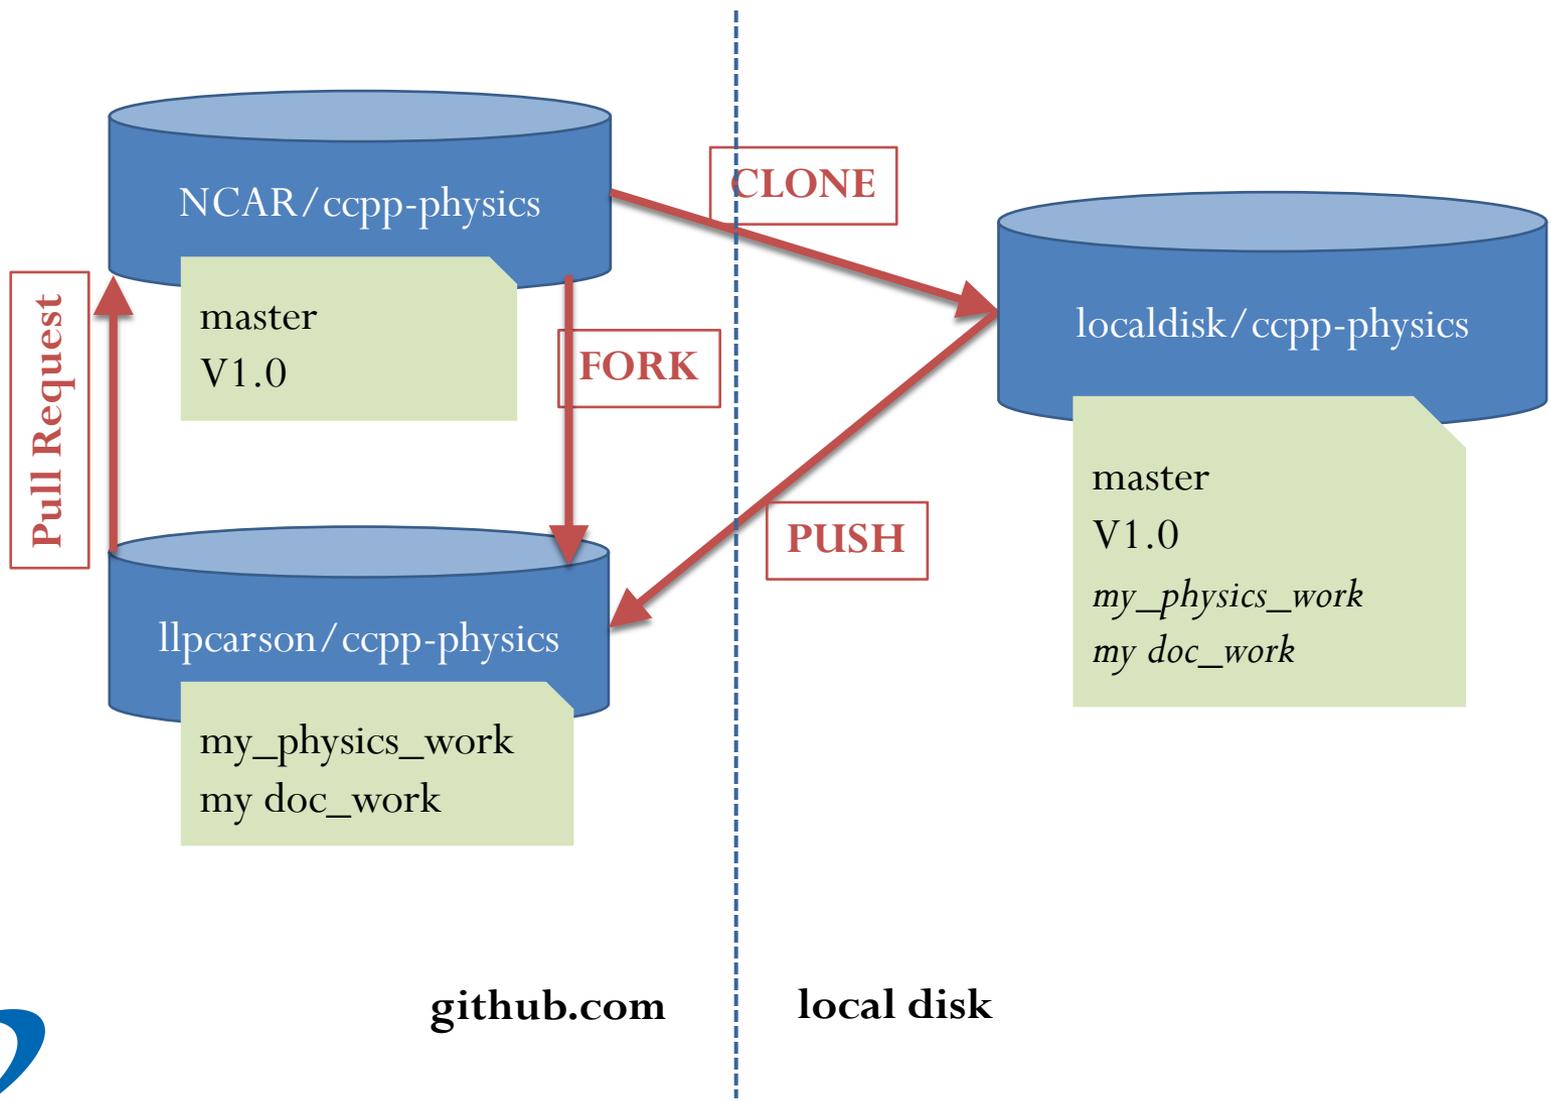

GitHub forking workflow

- CCPP is currently using a git forking workflow for the various code repositories
 - The GitHub forking workflow relies on forks (personal copies) of the shared repositories on GitHub.
 - These forks need to be created only once, and only for repositories that users will contribute changes to.
 - The use of forks and PRs (pull requests) are slightly different than the Vlab workflow – but many of the concepts are similar.
- Additional resources:
 - <https://www.atlassian.com/git/tutorials/comparing-workflows/forking-workflow>
 - <https://guides.github.com/activities/forking/>

GitHub forking workflow

Basic steps

1. Clone the authoritative repository locally
2. Create a local branch, add development, complete testing
 1. First time only: create your personal fork
3. Push local branch to your personal fork
4. Open a PR (pull request) to request a code review and merge with the authoritative repository

1. Clone the authoritative repository locally

- Clone a working copy of the authoritative repository on disk:
NEMSFv3gfs
 - This command creates a local cloned repository, checks out the branch named gmtb/ccpp, and recursively checks out the related submodules

```
% git clone --recursive -b gmtb/ccpp  
https://github.com/NCAR/NEMSFv3gfs
```

- RENAME the git remote from “origin” to “upstream”

```
% git remote rename origin upstream
```

1.A git submodules

- Submodules are a mechanism in git repositories to provide a link or connection to another repository
- Submodules are configured using the "git submodule" command, i.e.
 - git submodule init
 - git submodule update
 - git submodule add
- The linked repositories are listed in .gitmodules

```
[submodule "FV3"]
  path = FV3
  url = https://github.com/NCAR/FV3
[submodule "NEMS"]
  path = NEMS
  url = https://github.com/NCAR/NEMS
```
- Submodule repositories can also have submodules (recursive!)
- git subtrees are different 😊

1.B github authentication

- For private repositories, github.com will ask for authentication (username and password) to access the repository
- You may optionally configure SSH keys
 - From the upper-right user icon, select “settings”*
 - Select “SSH and PGP keys”
 - Follow the instructions here:

<https://help.github.com/en/articles/connecting-to-github-with-ssh>

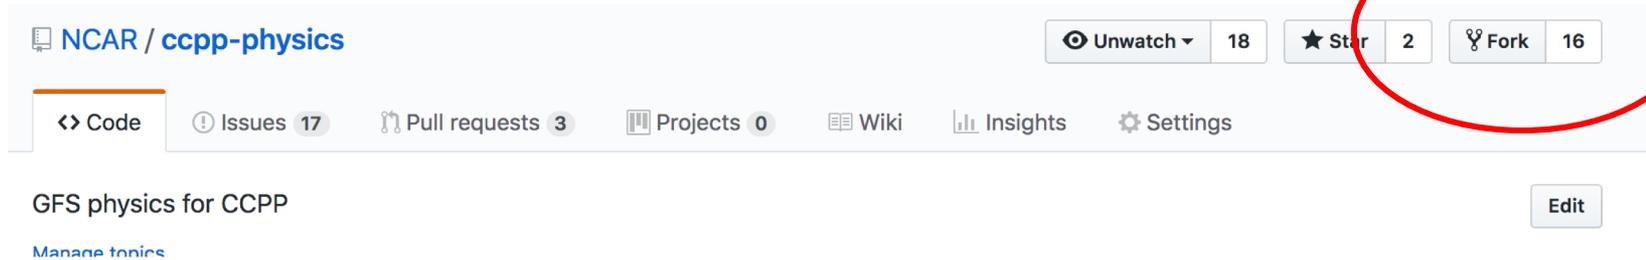

*There are many other useful settings here, including notifications, look around!

2. Create a local branch, add development, complete testing

```
% git checkout -b my_physics_work
```

- The “-b” makes a new branch for you. It will be a copy of the branch you are currently viewing (gmtb/ccpp)
- Use the usual git commands to add and commit

3. Push local branch to your personal fork

- Create a personal fork if you have not already done so!
- In your local repository on your local disk, add a remote called “origin” pointing to your local fork, and update (to check that the remote is configured correctly)
- `% git remote add origin https://github.com/YOUR_GITHUB_USER/ccpp-physics`
- `% git remote update`
- Then, push your local branch to your fork:

```
% git push origin my_physics_work[:my_physics_work]
```

4. Open a PR (pull request)

- Open a PR (pull request) to request a code review and merge

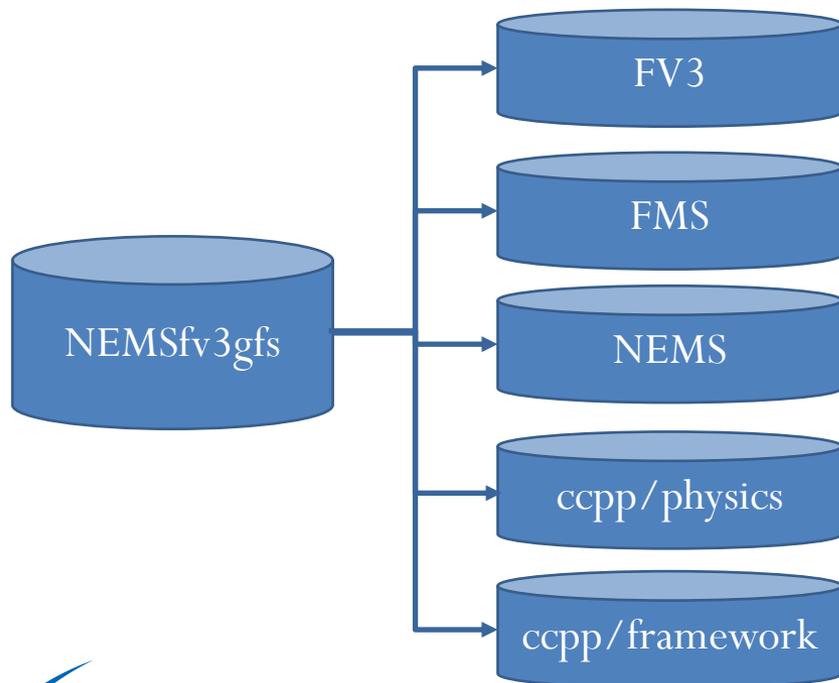

The screenshot shows the GitHub interface for the repository 'llpcarson / ccpp-physics', which is a fork of 'NCAR/ccpp-physics'. The repository name and 'forked from' text are circled in red. The navigation bar includes 'Code', 'Pull requests 0', 'Projects 0', 'Wiki', 'Insights', and 'Settings'. Below the navigation bar, the repository name 'GFS physics for CCPP' is shown with an 'Edit' button. A summary bar displays '624 commits', '9 branches', '7 releases', '6 contributors', and 'View license'. The 'Branch: version2name' dropdown is set to 'version2name', and a 'New pull request' button is visible. The 'Clone or download' button is highlighted in green. At the bottom, the text 'This branch is 1 commit ahead, 321 commits behind NCAR:master.' is shown, and a 'Pull request' button is circled in red.

A Pull Request is a GitHub-provided mechanism to request a code review, and merge changes into another branch or repository

NEMSFv3gfs and CCPP

Code repositories

- The repository structure for CCPP development in NEMSfv3gfs mirrors the Vlab repository structure, with the addition of the CCPP repositories

Repository (GMTB development version)	Branch name
https://github.com/NCAR/NEMSfv3gfs	gmtb/ccpp
https://github.com/NCAR/FV3	gmtb/ccpp
https://github.com/NCAR/ccpp-physics	master
https://github.com/NCAR/ccpp-framework	master
https://github.com/NCAR/NEMS	gmtb/ccpp
https://github.com/NCAR/FMS	GFS-FMS

How to get the code

- The authoritative repositories are located on github.com in the NCAR organizational space
 - Some repositories are private (NEMSFv3gfs, FV3, NEMS)
 - Some repositories are public (ccpp-physics, ccpp-framework, FMS)
 - Send a request to gmtb-help@ucar.edu to request access to the private repositories
- Clone a local copy of the repository to begin working, including submodules

```
git clone --recursive -b emc_training_march_2019 https://github.com/NCAR/NEMSFv3gfs
```

- Any Questions?
- Up next, how to compile, and what build options are available
