 Box&Whisker are 90,70,50,30,10 non-exceedance probability

Percentage of total water year volume occurring in each month

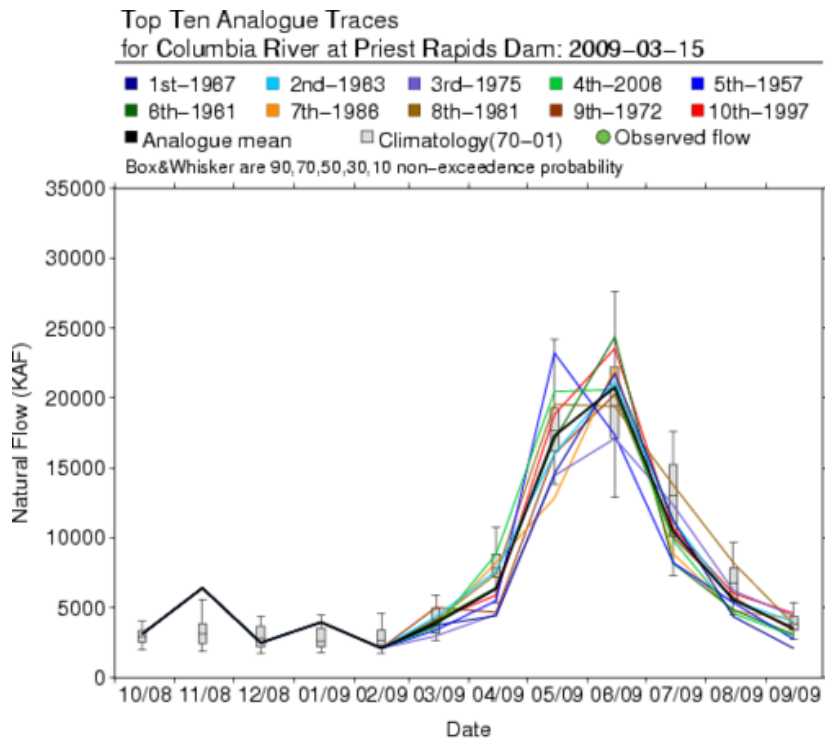

FCST:	3.7%	7.6%	3.0%	4.7%	2.5%	4.3%	8.6%	19.7%	21.7%	13.3%	7.0%	4.0%
CLIM:	3.3%	3.6%	3.3%	3.0%	3.0%	4.8%	9.0%	20.4%	22.4%	15.0%	7.8%	4.4%

- » Contain both deterministic and probabilistic elements
  - › Primarily based on deterministic forecasts
  - › With error climatology sampling (e.g. local quantile regression)

# User Feedback

- » Intervals and exceedance probabilities are typically not used
  - › Exceptions:
    - » avoid being caught short of water resource
    - » high confidence of low winds (maintenance)
  
- » Frequently Asked Questions:
  - › What does the upper/lower bound mean?
  - › How do I choose which forecast value to use?
  - › Does the prediction interval show the expected intra-period variability?
  - › Can the exceedance probabilities be changed (are they configurable)?

# Common Barriers To (Proper) Use

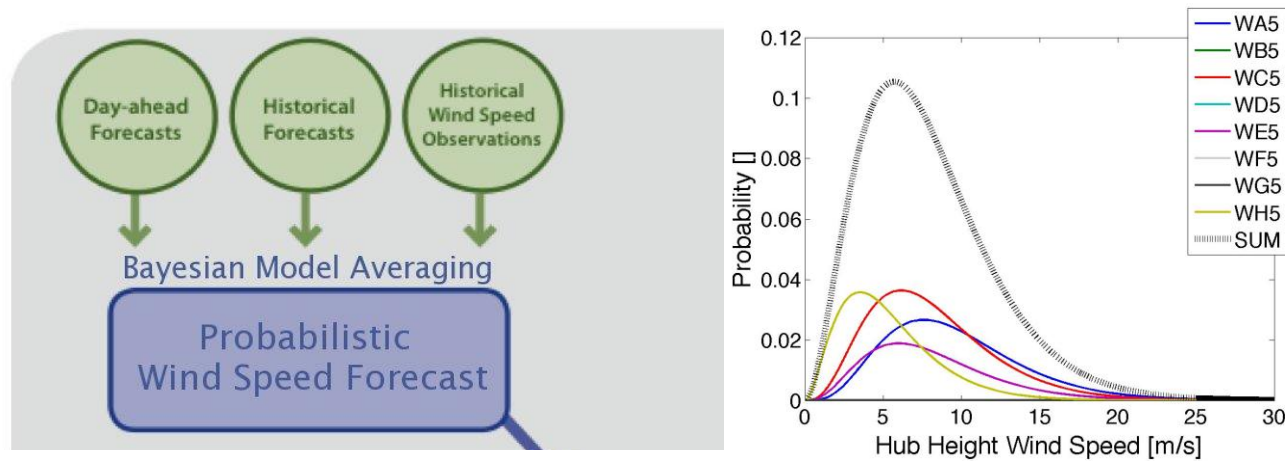

## Streamflow Scenarios / Analogs

- » Misunderstanding the forecast quantities
  - › Non-exceedance probability
    - “1 in 10 chance that the actual streamflow will be lower than this value”
  - › Temporal averaging period
    - “1-hour avg wind power generation”
- » Unknown client risk tolerance
  - › Changing economic factors
  - › Not quantifiable (too complex)  
(e.g., electric reliability is priceless)
- » Lack of interactivity
  - › Need to do scenario analysis

# Ensemble-Based Forecast Creation

- » Combined poor-person's ensemble with home-grown, mixed-physics WRF model ensemble (w/ out data assimilation)
  - › Used MOS and BMA to calibrate over (pseudo) re-forecast data set
  - › Event timing errors and missed events were still significant
  - › Need (client demand) for 0-6 hour estimates of event risk
- » Have avoided full-scale ensemble data assimilation and forecast system so far.

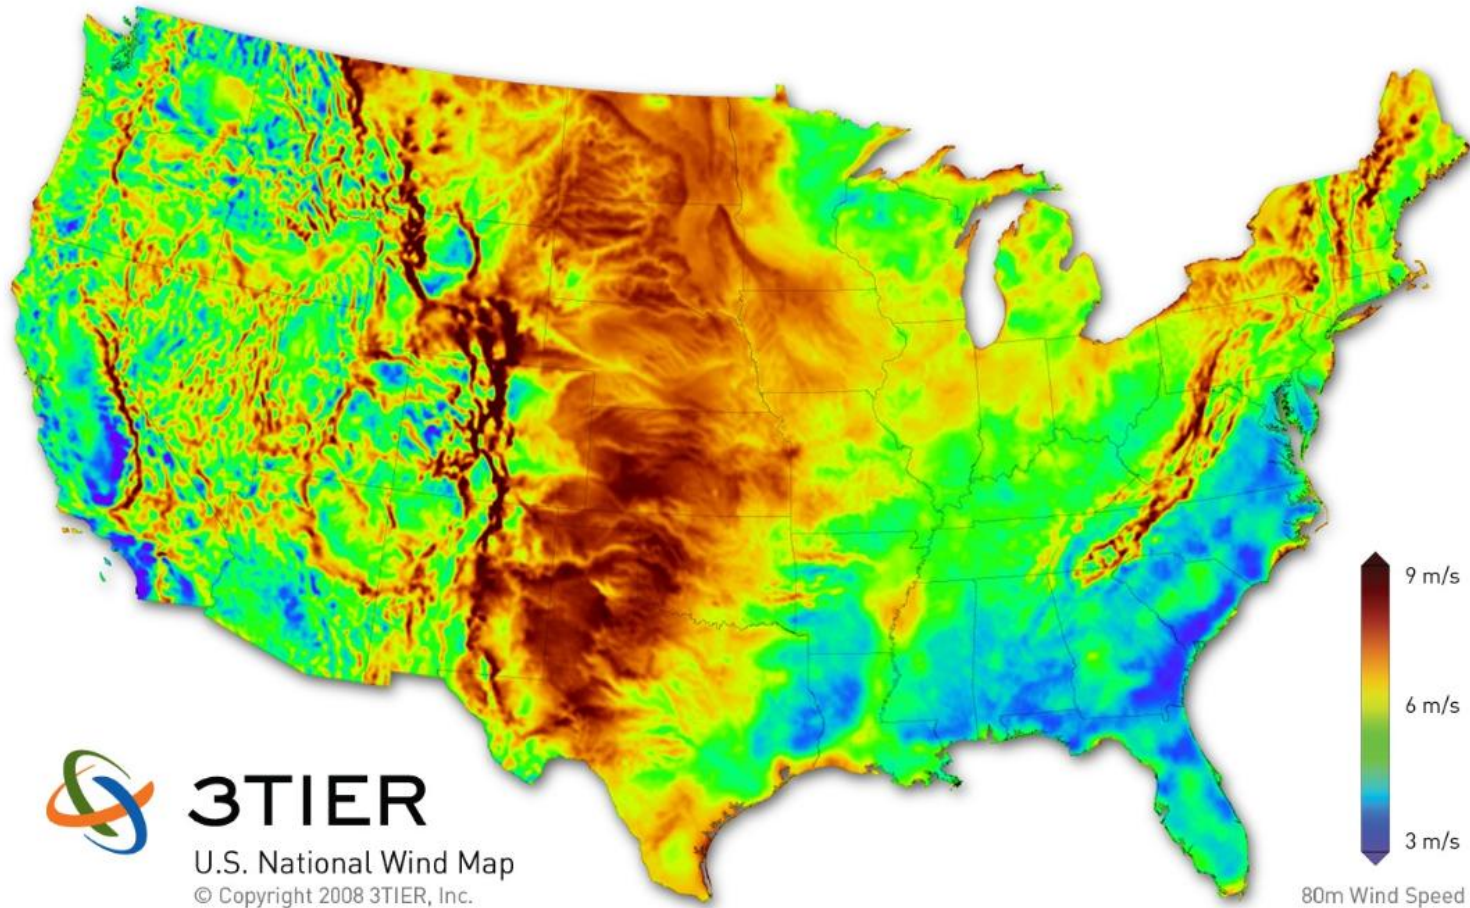

# Recommended MEPS/SREF Requirements

- » Improved Member Diversity in Short-Range (0-3 days)
  - › Especially needed at 0-6 hrs (ensemble/hybrid data assimilation)
  - › Needs to include lower BC uncertainties (ocean and land surfaces)
  
- » Comprehensive Data Availability, Including Re-Forecasts
  - › Full model output fields on native grid resolution at 1-hr. intervals
  - › Re-forecasts for at least 1 cycle, out to 3 days, over previous 3 yrs.
    - » invaluable for calibration and site-specific model development
  
- » Timeliness and Rapid Refresh
  - › Needs to be available within assimilation cycle period
  - › Becoming more important as utilities and grid system operators begin to ask for sub-hourly updates

# Closing Remarks

- » A stronger, cohesive U.S. NWP effort, which includes a rapidly refreshed, mesoscale ensemble data assimilation and prediction system, is needed to support the energy industry.
  - › Full gridded model output should be made available, if possible.
  
- » Industry-specific post-processing (calibrated products for industry decision-making) should be handled by the private sector.
  - › Hazardous weather and general public weather forecast post-processing should continue to be handled by NOAA.
  
- » Generalized ensemble forecast verification results performed in the energy industry ought to be shared with modeling system developers and the operational centers.

# Our Potential Is Vast

# Remaining Challenges

## » Technical Factors:

- › Timing errors are significant
  - » Improved ensemble prediction system (size and IC diversity)
  - » Incorporate time-shifting into BMA calibration
- › Finding regime-dependent training sets (analogs)

## » Human Factors:

- › User Interface Must:
  - » Convey understanding of the (coupled) forecast quantities
  - » Allow requests for user-defined quantiles or intervals
  - » Support interactive viewing of different requests
